Even the stones, though very hard, are not thrown away. They give them to their camels and sheep as food, after they have bruised them or laid them to soften in water.

The date, as well as other trees which are cultivated, exhibits great variety in its fruit, with respect to shape, size, quality, and even colour. There are reckoned to be at least twenty different kinds. Dates are very liable to be pierced by worms, and they soon corrupt in moist or rainy weather.

From what has been said, it may easily be perceived, that there is, perhaps, no tree whatever used for so many and so valuable purposes as the date tree.

PHOENIX, in ornithology, a bird famous in antiquity, but generally looked upon by the moderns as fabulous. The ancients speak of this bird as single, or the only one of its kind; they describe it as of the size of an eagle; its head finely crested with a beautiful plumage, its neck covered with feathers of a gold colour, and the rest of its body purple, only the tail white, and the eyes sparkling like stars: they hold,

that it lives 500 or 600 years in the wilderness; that when thus advanced in age, it builds itself a pile of sweet wood and aromatic gums, and fires it with the wafting of its wings, and thus burns itself; and that from its ashes arises a worm, which in time grows up to be a phoenix. Hence the Phœnicians gave the name of *phœnix* to the palm tree; because when burnt down to the root it rises again fairer than ever.

In the sixth book of the annals of Tacitus, sect. 28. it is observed that, in the year of Rome 787, the phœnix revisited Egypt; which occasioned among the learned much speculation. This being is sacred to the sun. Of its longevity the accounts are various. The common persuasion is, as we have mentioned above, that it lives 500 years; though by some the date is extended to 1451. The several eras when the phœnix has been seen are fixed by tradition. The first, we are told, was in the reign of Sesostris; the second in that of Amasis; and, in the period when Ptolemy the third of the Macedonian race was seated on the throne of Egypt, another phœnix directed its flight towards Heliopolis. When to these circumstances are added the brilliant appearance of the phœnix, and the tale that it makes frequent excursions with a load on its back, and that when, by having made the experiment through a long tract of air, it gains sufficient confidence in its own vigour, it takes up the body of its father and flies with it to the altar of the sun to be there consumed; it cannot but appear probable, that the learned of Egypt had enveloped under this allegory the philosophy of comets.

PHOENIX, son of Amyntor king of Argos by Cleobule of Hippodamia, was preceptor to young Achilles. His father having proved faithless to his wife, through fondness for a concubine called *Clytia*, Cleobule, who was jealous of him, persuaded her son Phoenix to ingratiate himself with his father's mistress. Phoenix easily succeeded; but Amyntor discovering his intrigues, he drew a curse upon him, and the son was soon after deprived of his sight by divine vengeance. Some say that Amyntor himself put out his son's eyes, which so cruelly provoked him that he meditated the death of his father. Reason and pity, however, prevailed over passion; and that he might not become a parricide, Phoenix fled from Argos to the court of Peleus king of Phthia. Here he was treated with tenderness; Peleus carried him to Chiron, who restored him to his eye-sight; soon after which he was made preceptor to Achilles, his benefactor's son. He was also presented with the government of many cities, and made king of the Dolopes. He went with his pupil to the Trojan war; and Achilles was ever grateful for the instructions and precepts which he had received from him. After the death of Achilles, Phoenix, with others, was commissioned by the Greeks to return into Greece, to bring to the war young Pyrrhus. This commission he successfully performed; and after the fall of Troy, he returned with Pyrrhus, and died in Thrace. He was buried, according to Strabo, near Trachinia, where a small river in the neighbourhood received the name of *Phoenix*. There was another Phoenix, son of Agenor, by a nymph who was called *Telephassa*, according to Apollodorus and Moschus, or, according to others, *Epimodusa*, *Perimeda*, or *Agriope*. He was, like his brother Cadmus, and Cilix, sent by
lus

Phoenix.

Pholas.

his father in pursuit of his sister Europa, whom Jupiter had carried away under the form of a bull; and when his inquiries proved unsuccessful, he settled in a country, which, according to some, was from him called *Phœnicia*. From him, as some suppose, the Carthaginians were called *Pœni*.

Plate
CCCXII.

PHOLAS, a genus of insects, belonging to the order of vermes testacea. The shell is double-valved and divaricated; the cardo is turned backwards, and connected by a cartilage. There are six species, distinguished by the figure of their shells.

The word *pholas* is derived from the Greek, and signifies something which lies hid. This name they derive from their property of making themselves holes in the earth, sand, wood, or stone, and living in them. The means of their getting there, however, are as yet entirely unknown. All that we can know with certainty is, that they must have penetrated these substances when very small; because the entrance of the hole in which the pholas lodges is always much less than the inner part of it, and indeed than the shell of the pholas itself. Hence some have supposed that they were hatched in holes accidentally formed in stones, and that they naturally grew of such a shape as was necessary to fill the cavity.

The holes in which the pholades lodge are usually twice as deep, at least, as the shells themselves are long; the figure of the holes is that of a truncated cone, excepting that they are terminated at the bottom by a rounded cavity, and their position is usually somewhat oblique to the horizon. The openings of these holes are what betray the pholas being in the stone; but they are always very small in proportion to the size of the fish. There seems to be no progressive motion of any animal in nature so slow as that of the pholas; it is immersed in the hole, and has no movement except a small one towards the centre of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion; but it has great time to perform it in, as it only moves downward, sinking itself deeper in the stone as it increases itself in bulk. That part by means of which it performs this, is a fleshy substance placed near the lower extremity of the shell; it is of the shape of a lozenge, and is considerably large in proportion to the size of the animal; and though it be of a soft substance, it is not to be wondered at that in so long a time it is able, by constant work, to burrow into a hard stone. The manner of their performing this may be seen by taking one of them out of the stone, and placing it upon some soft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themselves in the mud in as large a hole as they had taken many years to make in the stone. They find little resistance in so soft a substance; and the necessity of their hiding themselves evidently makes them hasten their work. The animal is lodged in the lower half of the hole in the stone, and the upper half is filled up by a pipe of a fleshy substance and conic figure, truncated at the end: this they usually extend to the orifice of the hole, and place on a level with the surface of the stone; but they seldom extend it any farther than this. The pipe, though it appears single, is in reality composed of two pipes, or at least it is composed of two parts separated

by a membranæ. The use of this pipe or proboscis is the same with that of the proboscis of other shell fish, to take in sea-water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a small green vessel, the use of which has not yet been discovered. This, when plunged in spirit of wine, becomes of a purple colour: but its colour on linen will not become purple in the sun like that of the murex; and even if it would, its quantity is too small to make it worth preserving.

The pholas is remarkable for its luminous quality. That this fish was luminous is noticed by Pliny, who observes that it shines in the mouth of the person who eats it; and if it touch his hands or clothes, it makes them luminous. He also says, that the light depends upon its moisture. The light of this fish has furnished matter for various observations and experiments to M. Reaumur and the Bolognian academicians, especially Beccarius, who took so much pains with the subject of phosphoreal light.

M. Reaumur observes, that whereas other fishes give light when they tend to putrescence, this is more luminous in proportion to its being fresh; that when they are dried, their light will revive if they be moistened either with fresh or salt water, but that brandy immediately extinguishes it. He endeavoured to make this light permanent, but none of his schemes succeeded.

The attention of the Bolognian academicians was engaged to this subject by M. F. Marilius in 1724, who brought a number of these fishes, and the stones in which they were inclosed, to Bologna, on purpose for their examination.

Beccarius observed, that though this fish ceased to shine when it became putrid, yet that in its most putrid state it would shine, and make the water in which it was immersed luminous when it was agitated. Galeatius and Montius found that wine or vinegar extinguished this light; that in common oil it continued some days, but in rectified spirit of wine or urine hardly a minute.

In order to observe in what manner this light was affected by different degrees of heat, they made use of a Reaumur's thermometer, and found that water rendered luminous by these fishes increased in light till the heat arrived to 45°, but that it then became suddenly extinct, and could not be revived again.

In the experiment of Beccarius, a solution of sea-salt increased the light of the luminous water; a solution of nitre did not increase it quite so much. Sal ammoniac diminished it a little, oil of tartar, *per deliquium* nearly extinguished it, and the acids entirely. This water poured upon fresh calcined gypsum, rock crystal, ceruse, or sugar, became more luminous. He also tried the effects of it when poured upon various other substances, but there was nothing very remarkable in them. Afterwards, using luminous milk, he found that oil of vitriol extinguished the light, but that of tartar increased it.

This gentleman had the curiosity to try how differently coloured substances were affected by this kind of light; and having, for this purpose, dipped several ribbons in it, the white came out the brightest, next to this was the yellow, and then the green; the other colours could hardly be perceived. It was not,

however,

Pholas.

Pholas,
Pholeys.

however, any particular colour, but only light, that was perceived in this case. He then dipped boards painted with the different colours, and also glass tubes filled with substances of different colours, in water rendered luminous by the fishes. In both these cases, the red was hardly visible, the yellow was the brightest, and the violet the dullest. But on the boards, the blue was nearly equal to the yellow, and the green more languid; whereas in the glasses, the blue was inferior to the green.

Of all the liquors to which he put the pholades, milk was rendered the most luminous. A single pholas made seven ounces of milk so luminous, that the faces of persons might be distinguished by it, and it looked as if it was transparent.

Air appeared to be necessary to this light; for when Beccarius put the luminous milk into glass tubes, no agitation would make it shine unless bubbles of air were mixed with it. Also Montius and Galeatus found, that, in an exhausted receiver, the pholas lost its light, but the water was sometimes made more luminous; which they ascribed to the rising of bubbles of air through it.

Beccarius, as well as Reaumur, had many schemes to render the light of these pholades permanent. For this purpose he kneaded the juice into a kind of paste with flour, and found that it would give light when it was immersed in warm water; but it answered best to preserve the fish in honey. In any other method of preservation, the property of becoming luminous would not continue longer than six months, but in honey it had lasted above a year; and then it would, when plunged in warm water, give as much light as ever it had done. See Barbut's *Genera Terminus*, p. 14. &c.

PHOLEYS, or FOULIES, are a people of Africa, of very peculiar manners. Some authors tell us, that the kingdom of Pholey, from whence they derive their name, is divided from that of Jaloff by a lake called in the language of the Mundingoes *Cayor*; and that it stretches from east to west about 180 miles; but that, though it extends a great way south, its limits in that direction are not exactly ascertained.

Mr Moore, however, gives a very different account, and says, that the Pholeys live in clans, build towns, and are in every kingdom and country on each side the river; yet are not subject to any of the kings of the country, though they live in their territories; for if they are used ill in one nation, they break up their towns, and remove to another. They have chiefs of their own, who rule with such moderation, that every act of government seems rather an act of the people than of one man. This form of government is easily administered, because the people are of a good and quiet disposition, and so well instructed in what is just and right, that a man who does ill exposes himself to universal contempt.

The natives of all these countries, not being avaricious of land, desire no more than they can use; and as they do not plough with horses or other cattle, they can use but very little; and hence the kings willingly allow the Pholeys to live in their dominions, and cultivate the earth.

The Pholeys have in general a tawney complexion, though many of them are of as deep a black as the

Mundingoes; and it is supposed that their alliance with the Moors have given them the mixed colour between the true olive and the black. They are rather of a low stature, but have a gent and easy shape, with an air peculiarly delicate and agreeable.

Though they are strangers in the country, they are the greatest planters in it. They are extremely industrious and frugal, and raise much more corn and cotton than they consume, which they sell at reasonable rates; and are so remarkable for their hospitality, that the natives esteem it a blessing to have a Pholey town in their neighbourhood; and their behaviour has gained them such reputation that it is esteemed infamous for any one to treat them in an inhospitable manner. Their humanity extends to all, but they are doubly kind to people of their race; and if they know of any one of their body being made a slave, they will readily redeem him. As they have plenty of food, they never suffer any of their own people to want; but support the old, the blind, and the lame, equally with the others.

These people are seldom angry; and Mr Moore observes that he never heard them abuse each other; yet this mildness is far from proceeding from want of courage, they being as brave as any people of Africa, and very expert in the use of their arms, which are javelins, cutlasses, bows and arrows, and upon occasion guns. They usually settle near some Mundingoe town, there being scarce any of note up the river that has not a Pholey town near it. Most of them speak Arabic, which is taught in their schools; and they are able to read the Koran in that language, though they have a vulgar tongue called *Pholey*. They are strict Mahometans, and scarce any of them will drink brandy, or any thing stronger than sugar and water.

They are so skilful in the management of cattle, that the Mundingoes leave theirs to their care. The whole herd belonging to a town feed all day in the savannahs, and after the crop is off, in the rice-grounds. They have a place without each town for their cattle, surrounded by a circular hedge, and within this enclosure they raise a stage about eight feet high, and eight or ten feet wide, covered with a thatched roof; all the sides are open, and they ascend to it by a ladder. Round this stage they fix a number of stakes, and when the cattle are brought up at night, each beast is tied to a separate stake with a strong rope made of the bark of trees. The cows are then milked, and four or five men stay upon the stage all night with their arms to guard them from the lions, tygers, and other wild beasts. Their houses are built in a very regular manner, they being round structures, placed in rows at a distance from each other to avoid fire, and each of them has a thatched roof somewhat resembling a high crowned hat.

They are also great huntsmen, and not only kill lions, tygers, and other wild beasts, but frequently go 20 or 30 in a company to hunt elephants; whose teeth they sell, and whose flesh they smoke-dry and eat, keeping it for several months together. As the elephants here generally go in droves of 100 or 200, they do great mischief by pulling up the trees by the roots, and trampling down the corn; to prevent which, when the natives have any suspicion of their coming, they make fires round their corn to keep them out.

They

Pholis
||
Phormium.

They are almost the only people who make butter, and sell cattle at some distance up the river. They are very particular in their dress, and never wear any other cloathes but long robes of white cotton, which they make themselves. They are always very clean, especially the women, who keep their houses exceedingly neat. They are, however, in some particulars very superstitious; for if they chance to know that any person who buys milk of them boils it, they will from thenceforth on no consideration sell that person any more, from their imagining that boiling the milk makes the cows dry.

PHOLIS, in natural history, is the name of a genus of fossils of the class of gypsums or plaster-stones. Its distinguishing characters are, that the bodies of it are tolerably hard, composed of particles somewhat broad, and of a bright crystalline lustre. The name is derived from *φολις*, a *scale* or *small flake*, because they are composed of particles of that form.

The species of this genus are very valuable, and perhaps the most so of all the gypsums, because they burn to the best and finest plaster, but so far as is yet known, there are but two of them: the fine plaster stone of Montmartre in France, called by us *plaster of Paris stone* and *parget*; and the other, the coarser and somewhat reddish kind, common in many parts of England, and called *hall plaster*. See *PLASTER of Paris*.

PHOLIS, in ichthyology, is the name of a small anguilliform fish. The back is brown, the belly is white, the whole back and sides are spotted, and the skin is soft, free of scales, but with a tough mucilaginous matter like the eel. This species most of all approaches to the *alnuda*; and tho' usually larger, yet Mr Ray doubts whether it really differs from it in any thing essential; the distinction is its colour, which though a very obvious is certainly a very precarious one.

PHONICS, the doctrine or science of sounds, otherwise called *Acoustics*. See that article.

PHORMIUM, FLAX-PLANT, (*Phormium tenax*, Forst.) is a name which we may give to a plant that serves the inhabitants of New Zealand instead of hemp and flax. Of this plant there are two sorts; the leaves of both resemble those of flax, but the flowers are smaller, and their clusters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of these plants, with very little preparation, they make all their common apparel, and also their strings, lines, and cordage, for every purpose; which are so much stronger than any thing we can make with hemp, that they will not bear a comparison. From the same plant, by another preparation, they draw long slender fibres, which shine like silk, and are as white as snow: of these, which are very strong, they make their finest cloths; and of the leaves, without any other preparation than splitting them into proper breadths, and tying the strips together, they make their fishing nets, some of which are of an enormous size.

The seeds of this valuable plant have been brought over into England; but, upon trial, appeared to have lost their vegetating power.

The filamentous parts of different vegetables have been employed in different countries for the same mechanic uses as hemp and flax among us. Putrefaction,

and in some degree alkaline lixivium, destroy the pulpy *Phormium*, or fleshy matter, and leave the tough filaments entire. *Phosphat.* By curiously putrefying the leaf of a plant in water, we obtain the fine flexible fibres which constituted the basis of the ribs and minute veins, and which form as it were a skeleton of the leaf. In Madagascar, different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in strong ley; and some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton: others are coarser and stronger, and last thrice as long as cotton; and of these filaments they make sails and cordage to their vessels. The stalks of nettles are sometimes used for like purposes, even in France; and Sir Hans Sloane relates, in one of his letters to Mr Ray, that he has been informed by several, that muslin and callico, and most of the Indian linens, are made of nettles. A strong kind of cloth is said to be prepared in some of the provinces of Sweden of hop-stalks; and in the transactions of the Swedish Academy for 1750, we have an account of an experiment relating to this subject: A quantity of the stalks was gathered in autumn, which was equal in bulk to a quantity of flax sufficient to yield a pound after preparation. The stalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a stove, and dressed as flax. The prepared filaments weighed nearly a pound, and proved fine, soft, and white; they were spun and wove into six ells of fine strong cloth. Unless the stalks are fully rotted, which will take much longer time than flax, the woody part will not separate, and the cloth will prove neither white nor fine.

PHOSPHAT, is a mineral found in Estremadura, It is of a whitish colour, and of great solidity, though not sufficiently hard to strike fire with steel. If triturated in an iron mortar in the dark, or even if two pieces of it be rubbed together, it becomes luminous; but when it has once lost this property, it does not, like some natural phosphori, receive it again by being exposed to the rays of the sun. If reduced to a very fine powder, and laid on coals, it does not decrepitate, but burns with a beautiful green light; though, if the coals be very hot, and the powder coarse, decrepitation will take place.

According to the analysis made by these chemists, 100 grains of the calcareous phosphat is resolvable into the following elements:

Carbonic acid	-	-	1 grain.
Muriatic acid	-	-	$\frac{1}{2}$
Iron	-	-	1
Quartzous earth	-	-	2
Pure calcareous earth	-	-	59
Phosphoric acid	-	-	34
Fluoric acid	-	-	$2\frac{1}{2}$
			100 Grains.

We have the following account of an analysis of a native phosphat of lime (earth bones) by Mr Haffentratz in the *Annals of Chemistry*. "The phosphat of lime of estremadura, found by Mr Proust, determined me to examine on the coals a phosphorescent powder which I collected at Kobala-Polyana near Sigeth,

Phosphat, Phosphorus, Sigeth, in the county of Marmarosch, during the metallurgic tour I made through Hungary by command of government. Though this powder gives absolutely the same appearance when treated on the coals as the fluat of lime (*spath-fluor*), yet no fluoric acid is disengaged from it when heated with sulphuric acid. It dissolves in nitric acid (dephlogisticated nitrous acid); and sulphuric (vitriolic) acid precipitates from this solution a considerable quantity of sulfat of lime (gypsum): the liquor filtered, and concentrated by evaporation, gives a new precipitate similar to the former. The liquor again filtered, and evaporated to dryness, left a slight residuum. This residuum, after having been exposed to a fire sufficiently strong to make the vessel containing it red-hot, and disengage the nitric and sulphuric acids which might have remained united with it, was soluble in distilled water, which it acidified. This acid did not precipitate barytic muriat; it caused a white precipitate from the solutions of sulfat of iron (green vitriol), and nitrat of mercury (mercurial nitre), and formed a thick and copious one in lime water: hence it is evident, that this acid was the phosphoric, and the powder was phosphat of lime."

The phosphat of soda is obtained by combining the phosphoric acid with the mineral alkali. It has, we are told, been given with success as a purge; and M. Pelletier thinks it may be applied to the soldering of metals instead of borax; and indeed it resembles this substance so much in many of its properties, that it has been supposed that phosphoric acid is one of the constituent principles of borax. See CHEMISTRY, n^o 904.

1
Phosphorus defined and distinguished.

PHOSPHORUS, a name given to certain substances which shine in the dark without emitting heat. By this circumstance they are distinguished from the *pyrophori*, which though they take fire on being exposed to the air, are yet entirely destitute of light before this exposure.

2
Divided into various kinds.

Phosphori are divided into several kinds, known by the names of *Bolognian phosphorus*, *Mr Canton's phosphorus*, *Baldwin's phosphorus*, *phosphorus of urine*, &c. of which the last is by far the most remarkable both with respect to the quantity of light which it emits, and its property of taking fire and burning very fiercely upon being slightly heated or rubbed. For the method of preparing these, see *CHEMISTRY-Index*.

3
Divided into two classes.

Besides these, however, it has been found that almost all terrestrial bodies, upon being exposed to the light, will appear luminous for a little time in the dark, metals only excepted. This points out a general division of the phosphori into two classes; namely, such as require to be exposed to the light either of the sun or of some artificial fire, before they become luminous; and such as do not. Of the former kind are the *Bolognian phosphorus*, *Mr Canton's phosphorus*, the phosphori from earths, &c. Of the latter kind are *rotten-wood*, the skins of fishes, and the phosphorus of urine. To these we may add some other substances which become luminous in another way; *viz.* the mass which remains after the distillation of volatile sal ammoniac with chalk, leaf-sugar, and the phosphorus of urine dissolved in spirit of wine. The first, which is a composition of the marine acid of the sal ammoniac with the chalks, after being fused in a crucible, becomes luminous when

struck with any hard body; white sugar is luminous when grated or scraped in the dark; and the solution of phosphorus in spirit of wine is luminous only when dropped into water; and even then the light is only perceived where the drops fall into the liquid. One part of phosphorus communicates this property to 600,000 parts of spirit of wine.

There is a remarkable difference between the light of rotten wood, fishes, and that of phosphorus of urine, even when it is not in an ignited state; for this last does not cease to be luminous even when included within an exhausted receiver; the contrary of which happens to rotten wood and fishes. If air is strongly blown upon this phosphorus from a pair of bellows, it will extinguish its light for some time, which is not the case with the other kinds. When kept in water, and placed in a warm air, the phosphorus of urine discharges such large and bright flashes into the air above it, as are apt to surprise and even frighten those who are unacquainted with it. These eruptions are contracted in their passage through the water, but expand as soon as they get above it; however, the experiment can only be tried to advantage in warm weather, and in a cylindrical glass not above three quarters filled with water.

The phenomena exhibited by the earthy phosphori are very curious; both on account of the singular circumstances in which they exhibit their light, and the varieties observed in the light itself. All these, as has been already mentioned, emit no light till they have been first exposed to the light of the sun, or some other luminous body. After that, they are luminous in the dark for a considerable time; but by degrees their light dies away, and they emit no more till after another exposure to the sun. But if this happens to be too long continued, they are then irrecoverably spoiled. The same thing will happen from being too much heated without any exposure to light. Indeed, if a phosphorus, which has just ceased to be luminous, be heated, it will again emit light without any exposure to the sun; but by this its phosphoric quality is weakened, and will at last be destroyed. Indeed these phosphori are so tender, and impatient either of light or heat, that the best method of rendering them luminous occasionally is by discharging an electric bottle near them. The light of the flash immediately kindles the phosphorus, and it continues luminous for a considerable time, after which it may again be revived by another flash, and so on. However, with all the care that can be taken, these phosphori are very far from being perpetual; nor has any method been yet fallen upon to render them so.

The singularities in the light of the phosphori above mentioned are, that they emit light of many different and most beautiful colours. This difference of colours seems to be natural to them; for some will at first emit a green, others a red, others a violet, &c. at their formation. However, the best kinds agree in this strange property, that if they are exposed to a red light, they emit a red light in the dark; and the same of other colours. But this must not be understood without limitation; nor is the phosphoreal light at any time so bright as the luminous body, whatever it was, by which it was kindled. Neither are we to imagine, that any particular phosphorus has a particu-

Phosphorus lar kind of light appropriated to it; for the same phosphorus which at one time emits a purple light, will at another perhaps emit a green, or a light of some other colour.

6 The nature of phosphoric phenomena explained. The explanation of the principal phenomena of phosphorus is deducible from what has been shown concerning the nature of fire, compared with what is mentioned under the article **QUICKLIME**. Under this last article it is shown, that, when calcareous earths are deprived of their fixed air, a proportionable quantity of active fire is absorbed by them; that is, the ethereal fluid which pervades all bodies, has a violent tendency to expand itself, or to act all around every particle of the calcined earth, as from a centre. Of consequence, if this tendency was not counteracted by some other power, these substances would emit a perpetual flame. This power, however, is found in our atmosphere; which has already been shown either to be the positive principle of cold, or to contain it*. Hence, the latent fire in these substances is checked, and cannot act, excepting within the very substance itself. But if any other body comes in contact with the calcined earth, in which the principle of cold is less vigorous than in the atmosphere, the active fire in the quicklime immediately shows itself, and the body either becomes hot, or is consumed as if by fire. Hence it will follow, that if a very inflammable body is touched by quicklime, it ought to be set on fire. But of this we have no instance, because it is impossible for the quicklime to part with any of its fire, unless it receives something in exchange. This indeed it might receive from the atmosphere; which could supply it either with more fire, if it was in a state of ignition; or with fixed air, if any substance was at hand to receive the fire. But the atmosphere refuses to part with the fire which it contains, because the effort of the fire in the quicklime is not sufficiently strong to overcome the opposition it meets with in other bodies; and, on the other hand, the effort of the fire in the quicklime is sufficient to keep the earth from attracting fixed air out of the atmosphere. But when water, for instance, is poured on the quicklime, the dry earth absorbs it very greedily, and parts with a proportionable quantity of its latent fire, which the water also absorbs much more readily than the atmosphere. Hence the mixture becomes so exceedingly hot as sometimes to fire combustible bodies. Now if, instead of water, we suppose the lime to be mixed with oil, this also will absorb the fire, but not with such force as the water; neither is the heat by any means so considerable; because oil is capable of detaining a vast quantity of heat in a latent state, the only consequence of which is an increase of its fluidity, without any very perceptible change of temperature. At the same time, however, we must remember, that if the oil is in very small quantity, and intimately combined with the quicklime in that peculiar state which was formerly called *phlogiston*, it is easy to conceive, that it may be so much saturated with fire, as to be unable to contain any more without being ignited. In this case, if more fire is forced into the compound, a quantity of the phlogistic matter which it contains will be decomposed; and of consequence, the fire which it has imbibed will be thrown out, as in the common ignition of vapour; and in proportion to the degree of heat thus communicated, will the degree of ig-

* See the article 6429.

nition and the continuance of it be. If the quantity of heat is very great, the phlogiston will be dissipated all at once; but if otherwise, the ignition will continue for a much greater length of time, as is the case with a common fire.

To apply this to the accension of phosphori, we must consider that these substances, are all formed by calcining calcareous substances, and combining them with some portion of phlogistic matter. Baldwin's phosphorus is made by dissolving chalk in the nitrous acid, afterwards evaporating the solution, and driving off most of the acid. The consequence of this is, that the earth is left in an exceedingly caustic state, as the acid expels the fixed air more completely than could be done almost by any calcination whatever; at the same time that any phlogistic matter which might have been contained in the mixture is most accurately diffused through it, and combined with it. The Bolognian phosphorus is composed of a gypseous earth, which contains a quantity of vitriolic acid; and as no mineral is to be found perfectly free from phlogistic matter, the vitriolic acid unites with it during the calcination into an exceedingly inflammable sulphur; for the greater the quantity of acid there is in proportion to the phlogiston, the more inflammable is the compound †. Thus the Bolognian, as well as Baldwin's phosphorus, is a compound of quicklime and inflammable matter; and the case is still more plain with regard to Mr Canton's, where the quicklime is mixed with sulphur, and both calcined together.—Neither are the phosphori made by calcining oyster-shells without addition to be accounted any way different from those already mentioned; since the shells always contain some portion of inflammable matter, which, being reduced to a coal by the action of the fire, furnishes a quantity of phlogiston, and imparts it to the whole of the calcareous matter.

8 Having thus seen that the phosphori of which we now speak are all composed of pure calcareous earth and phlogiston, we are next to consider, that the phlogiston must be in such a state as it is when saturated with fire and ready to inflame. It is not indeed in the state of vapour, because this would require a quantity of fire detached from any other substance, and interposed between the particles of the vapour, in order to keep them at a distance, or to give it elasticity. But the fire which ought to do this is confined by the calcareous earth, which also detains the phlogiston itself. As long therefore as the balance is thus preserved, the phosphorus cannot shine; but as soon as a fresh quantity of light is discharged upon it, then more light or fire (for they are the very same in this case) enters the quicklime than it can contain. The consequence of this is, that the quantity which cannot be retained by the earth, exerts its force upon the phlogiston; which having already as much as it can hold, not only the superfluous quantity is discharged, but also part of that which the phlogiston had absorbed before. The burning indeed is very slow and weak, because the phlogiston is obstinately retained by the earth, which both impedes the ignition, and prevents the dissipation of the phlogiston in vapour. However, as soon as the lime has by its action impeded the farther extrication of the phlogiston, the balance is restored, the fire goes out, and the phosphorus ceases to be luminous. Heat will

Phosphorus

† See the article **SULPHUR**.

8 State of the phlogiston,

Phosphorus will kindle it again; but thus a larger quantity of phlogistic matter is dissipated, and the phosphorus is soon destroyed. Light does the same, but in a much more moderate degree; and therefore the phosphorus may be frequently rekindled by means of light, and will continue its splendor for a long time. But if the light is too long continued, or too violent, it will produce the same consequence whether it is attended with perceptible heat or not.

9
Particulars
respecting
phosphorus
of urine.

With regard to the phosphorus of urine, the case is the same; only, instead of the calcareous earth, we have here an acid joined with phlogiston. The latter is in exceeding small quantity, and of consequence so loaded with fire that the least additional heat, rubbing, or alteration in the weather, forces more fire upon it than it can bear, and therefore part of it is continually flashing off in these convulsions formerly mentioned. The reason why this phosphorus flashes like lightning, and the others give only a steady light like coals, is, that the compound is very volatile. It requires indeed a violent fire to distil it at first; but in the distillation so much fire is imbibed, that it seems ever afterwards ready to evaporate spontaneously; and therefore phosphorus, when once made, is easily redistilled in close vessels.

10
Why it
shines un-
der water.

It now remains only to show the reason why the phosphorus of urine and some others will shine under water, or in an exhausted receiver, while rotten wood, &c. will not. This seems to arise from the quantity of fire which they have *internally*, and which requires no supply from the external air, as in the case of common fire: and hence the phosphorus of urine shines more briskly *in vacuo* than in the air; because the pressure of the atmosphere is then taken off, and the evaporation of the phlogistic matter promoted. The light of fishes and rotten wood seems to be of an electric nature; and therefore ceases when the air is exhausted, as on this fluid all the phenomena of electricity are found to depend.

11
Cause of
the various
colours of
phosphoric
light.

With regard to the various colours of phosphoric light some have imagined that the earthy substance was capable of imbibing a certain quantity of light, and emitting it afterwards in the very same state, and having the same colour which it had before. But this is now known to be a mistake, and the light of the phosphori is found to be owing to a true accension, though weak, as in other burning bodies. Hence it is very probable that the colour of the light depends upon the degree of accension; for we see that even in common fires the colour depends in a great measure on the strength of the flame. Thus the flame of a candle, where it is not well kindled at bottom, always appears blue. The flame of a small quantity of sulphur, or of spirit of wine, is blue; but if a large quantity of either of these substances be set on fire, the flame will in many places appear white. A strong flame mixed with much smoke appears red; a weak one in similar circumstances appears brown, &c.—Hence if the phosphoric is weakly kindled it will emit a brown, violet, blue, or green flame; if strongly, a red or white one.

It has already been mentioned, that almost all terrestrial bodies have a phosphoric quality: however this, in most of them, is extremely weak, and continues

only for a very short time. Signor Beccaria, who discovered this property, in order to find out what substances were phosphoric and what were not, had a machine contrived like a dark lantern, in which he included himself, in order to perceive with the greater facility any small quantity of light which might be emitted by the substances which he designed to examine. In the side of the machine was a cylinder capable of being turned about without admitting any light. Upon this were passed the substances he designed to examine, and by turning the cylinder he immediately brought them from the light of the sun into intense darkness; in which situation there were but few substances which did not afford a sufficient quantity of light to render themselves visible. This phenomenon, however, is evidently similar to an optical illusion by which we are made to see what is not present before us; for if we look very intensely upon any thing for some time, suffering no more light to enter our eyes than what is reflected from that object, we will imagine that we still see it, though we remove into the dark or shut our eyes. The reason of this is, that the nervous fluid being once put in motion after a certain manner, continues that motion for a short space of time after the moving cause is removed. In like manner, as the light is partly reflected from bodies, and partly penetrates them, when any body is exposed to the light, and then is suddenly brought into a dark place, the ethereal fluid within its substance being once put into motion does not cease to move immediately, but for a time produces that vibration which we call *light*: for the substance of light is present in the most intense darkness as well as in sunshine. Hence almost all substances are capable of emitting light in the dark, after being exposed to a vigorous sunshine; though the reason of their doing so may be very different from that by which the phosphori becomes luminous.

Phosphorus
12
Signor
Beccaria's
experiment

Many entertaining experiments may be made with the various kinds of phosphori, especially with that of urine. This last, however, is sometimes dangerous on account of the violence with which it burns. If dissolved in oil of cloves, it loses this property, but continues to be as luminous as before; so that this mixture, called *liquid phosphorus*, may be used with safety. As on some occasions it may be wished to have it in powder, it is proper to observe that this may be done with safety by pouring some hot water upon the phosphorus in a glass mortar. The compound melts, and while in a soft state is easily reducible to powder of any degree of fineness.

13
Other ex-
periments.

Mr Margraff endeavoured to combine phosphorus with metals by distillation; but zinc and copper were the only two metals that showed any signs of combination (See CHEMISTRY, n^o 1413.) The great analogy, however, that has been observed between the properties of phosphorus and those of sulphur and arsenic, induced M. Pelletier long ago to suspect, that phosphorus would really combine with metals, and that the essential point was to retain the phosphorus in contact with the metal in a state of fusion. This happy idea led him to a method from which he has obtained all the success that could be desired. Of this we have already given a very contracted account after the word *Phosphorus*

14
On the
combina-
tion of
phosphorus
with met-
als.

Phosphorus *phorus* in the *Indes* to our article CHEMISTRY, we shall now extend that account, by giving that in the first volume of *Annals of Chemistry*.

15 Phosphoret of gold. "Each of the combinations which are now to be described, M. Pelletier has termed *phosphorated metal*.

"M. Pelletier mixed half an ounce of gold of parting, in powder, with an ounce of phosphoric glass and about a dram of powdered charcoal; he put this mixture into a crucible, covering it with a small quantity of charcoal powder; and then applied a degree of heat sufficient to melt the gold. During the operation, a considerable quantity of vapours of phosphorus was disengaged, but all the phosphorus which was produced was not dissipated; a small quantity united with the gold, which was whiter than in its natural state, broke under the hammer, and had also a crystallized appearance.

"Twenty-four grains of this phosphoret of gold, placed on a cupel in a heated muffle, lost only one grain, and the button of gold that remained had the peculiar colour of that metal.

16 Of Platina. "A mixture, consisting of an ounce of platina, an ounce of phosphoric glass, and a dram of powdered charcoal, being put into a crucible, and covered with a little charcoal powder, M. Pelletier gave it a degree of heat nearly equal to what would have fused gold: this he continued for an hour. Having broken the crucible, he found underneath a blackish glass a small button of a silver white, weighing more than an ounce. On the inferior part of the button were well defined crystals of the same substance, the figure of which was a perfect cube. The same experiment, frequently repeated, constantly afforded the same result.

"The phosphoret of platina is very brittle, pretty hard, and strikes fire with steel: it is not acted upon by the magnet, and when it is exposed naked to a fire capable of fusing it, the phosphorus is disengaged, and burns on its surface. Exposed to the fire in a cupelling furnace on porcelain tests, the phosphoret of platina leaves a black glass, which surrounds the metallic substance. The colour of the glass is owing to iron contained in the platina; and if it continue exposed to the same heat in fresh tests, the portions of glass that form latterly have not so deep a colour, are more or less greenish, have sometimes a bluish tinge, and become at last of a transparent white. This observation led M. Pelletier to imagine, that phosphorus was well adapted for separating iron from platina, and that it was one of the best means of separating it entirely from that metal. But the glass which results from the combustion of the phosphorus and its combination with the *oxyd* (calx) of iron, forms a crust which obstructs the combustion of the phosphorus that still remains combined with the platina. To overcome this obstacle, M. Pelletier thought of exposing the phosphoret of platina to the fire, in cupels made of calcined bones, which, as they easily absorb the glass of lead, ought also to have the property of absorbing the phosphoric glass. He repeated the operation, therefore, several times successively, changing the cupel. A button of platina, which had been thus operated on four times, he presented to the academy: in this state it was capable of being reduced into plates, but was brittle when heated.

Phosphorus "Since the reading of his memoir, M. Pelletier has pursued his process, and has advanced so far as to be able totally to free the platina from the phosphorus, so that it may be worked when heated: thus he has procured us a method of purifying this metal more advantageous probably than any hitherto attempted. The phosphoret of platina detonates strongly when it is thrown on nitre in fusion. A mixture of phosphoret of platina, and oxygenated muriat of potash (*dephlogisticated digestive salt*), thrown into a red hot crucible, produces a brisk detonation, and the platina remains pure in the crucible.

17 Of silver. "Half an ounce of silver, treated with an ounce of phosphoric glass and two drams of charcoal, acquired an increase of weight of one dram. The phosphoret formed was white: it appeared granulated, and as it were crystallized: it broke under the hammer, but was capable of being cut with a knife. Placed in a cupel in a heated muffle, the phosphorus was disengaged, and the silver remained quite pure.

18 Of copper. "In preparing phosphorus in the large way, M. Pelletier observed, that the phosphoric acid attacked in some degree the copper basons, which are in other respects very convenient for this operation; and in the retorts which he made use of for the distillation, he found phosphoret of copper, sometimes in small distinct grains, at others in large masses, according as the degree of heat which finished the operation was more or less intense. This phosphoret he exhibited to the academy, and thence it was mentioned in the chemical nomenclature. The phosphoret of copper is also obtainable by a process similar to that which we have described for obtaining that of gold, silver, and platina. The proportions which M. Pelletier employed were an ounce of shreds of copper, an ounce of phosphoric glass, and a dram of powdered charcoal. This phosphoret appears whitish, is sometimes variegated with the different colours of the rainbow; changes on exposure to the air like pyrites, loses its lustre, and assumes a blackish hue.

"Margraff had formed phosphoret of copper by distilling the oxyd of copper, called *crocus werneris*, with phosphorus; and M. Pelletier also obtained it by the same process: but he did not observe the property attributed to it by Margraff, of running when applied to a candle. Having placed the phosphoret in a cupel in a heated muffle, it was fused, the phosphorus inflamed on its surface; a blackish substance resembling scorix remained in the cupel, which was penetrated with a glass that gave it a blue colour.

"The phosphoret of iron produced by the fusion of an ounce of phosphoric glass, and an ounce of shreds of iron, mixed with half a dram of powdered charcoal, was very brittle, and broke white, with a striated and granulated appearance: in one cavity it was crystallized in rhomboidal prisms. It is the same substance which Bergman conceived to be a peculiar metal.

"This phosphoret, placed in a cupel in a heated muffle, soon entered into a state of fusion; in the cupel remained a brittle substance, which is an oxyd of iron, and the cupel was penetrated with a matter similar to that which M. Pelletier had observed on treating in the same manner phosphoret of platina, obtained from platina not purified.

"The

Phosphorus
19
Of lead.

"The phosphoret of lead, obtained by the process already described, appears little different from common lead. It is malleable, and easily cut with a knife, but it loses its lustre sooner than lead, and when melted on charcoal by the blow-pipe, the phosphorus burns, leaving the lead behind.

20
Of tin.

"The phosphoret of tin, which M. Pelletier obtained by his process, was divided into several grains, because he had not given a sufficient degree of fire to unite them. These grains did not appear different from the metal itself; but being melted with the blow-pipe, the phosphorus burnt on the surface of the metal, as in the similar experiment with lead.

"In fusing tin or lead with the charcoal powder and phosphoric glass, care must be taken not to urge the fire, as the phosphorus easily flies off from either of those metals.

"From the experiments of M. Pelletier, it appears that phosphorus may be combined with gold, platina, silver, copper, iron, tin, and lead; and that it deprives the five former metals of their ductility. M. Pelletier proposes to make further experiments, to ascertain whether it be possible or not to combine a greater quantity of phosphorus with the two latter, and whether they will retain their malleability in that case. In another memoir he will examine the action of phosphorus on semimetals: he proposes also to ascertain the order of its affinity with the metals and semimetals.

"It is much to be wished that M. Pelletier may carry to perfection a work which will enrich chemistry with a species of combination hitherto almost entirely unknown, and which he has discovered means of effecting by a process equally simple and ingenious."

In the 10th volume of the same Annals we find an account of the action of lime, and of some metallic oxyds on phosphorus, by Dr Raymond.

21
M. Gengembre's discovery of a peculiar kind of gas.

22
The process varied.

M. Gengembre discovered, that by boiling phosphorus in a solution of potash, a peculiar kind of gas was produced, which had the singular property of taking fire on coming into contact with the atmosphere, and to which the French chemists have given the appellation of *phosphorized hydrogen gas*. Dr Raymond thought of varying the process, in order to discover whether this gas might not be produced in some other way. He took two ounces of lime slaked in the air, a dram of phosphorus cut small, with half an ounce of water, which he mixed up into a soft paste, and put into a stone retort; to this retort a tube was fitted, the internal diameter of which, he says, ought not to exceed a line and a half, communicating with a receiver full of water. As soon as the retort was well heated, the phosphorized hydrogen gas was generated so abundantly, that, from the quantity of ingredients here mentioned, no less than three quarts of it were obtained. The residuum was found to have all the characters of the native phosphat of lime. Hence the Doctor supposes, that the water was decomposed during the process, and that its oxygen served to acidify the phosphorus; which, in this state, was combined with the lime, and formed the phosphat; while its hydrogen, assuming a gaseous state, carried with it a part of the phosphorus, to which the property of taking fire by contact with the air must be ascribed. The gas soon loses this property, and the phosphorus is

condensed on the sides of the receiver: great caution, however, is necessary; for though a part of the gas may seem to have deposited its phosphorus, and to be reduced to pure hydrogen, yet another part, in the same receiver, may retain enough to cause a formidable explosion, when in contact with air.

The facility with which water was thus decomposed led the author to suspect that a similar effect might be produced by the same mixture in the mean temperature of the atmosphere. Accordingly he found that in ten days time a small quantity of hydrogen gas was generated in the vials, in which the ingredients were placed: this, however, was not phosphorized, the heat not being sufficient to volatilize the phosphorus.

Animated by this success, Dr Raymond resolved to try what could be effected by metallic oxyds. He made two mixtures like the former; but instead of lime, he substituted in the one the white oxyd of zinc, and in the other the black oxyd of iron. After long distillation with great heat, he obtained from both phosphorized hydrogen gas; but it was produced in much less time, and in greater quantity, from the oxyd of zinc than from that of iron; which he ascribed to the close affinity of the former to the phosphoric acid.

23
Another variation.

In the 12th volume of the same valuable work, we have an account of a process for making Kunkel's phosphorus from urine, which is shorter and more economical than that by which Messrs Scheele and Ghan extract it from the bones of animals, by M. Giobert. This method is founded on the property of the metallic salts to separate the phosphoric acid from urine, which Margraff, we believe, first discovered: but M. Giobert has greatly improved on the process directed by the German chemist, as he avoids the tedious and disgusting operations of evaporating the urine, and exposing it to putrefaction. He tells us, that it is indifferent whether the urine be that of healthy or diseased persons; and that of horses is nearly as good for this purpose as that which is human. He gradually pours into it a solution of lead in the nitric acid, till the precipitation ceases which this had occasioned; the whole is then diluted with a considerable quantity of water, and afterward filtrated through a linen cloth. The precipitate, which is phosphat of lead, must be made up into a paste with powder of charcoal, and well dried in an iron or copper pan: it must afterward be distilled; when it will yield, first, an ammoniacal, and then an empyreumatic oil; these oils proceed from the urine, from which it is difficult to purify the phosphat. As soon as the oil ceases to come over, a clean receiver must be applied, and the fire be greatly increased. The phosphorus generally appears in about half an hour; and, within eight hours, twelve or fourteen ounces of it may thus be obtained. If the process be conducted with care, M. Giobert thinks that a hundred parts of phosphat of lead will yield between fourteen and eighteen of phosphorus.

24
Process for making Kunkel's phosphorus from urine.

If on the phosphat of lead thus precipitated from urine, a solution of sulphat of ammoniac be poured, and this, after digesting during twelve hours, be filtrated and evaporated, phosphat of ammoniac will be obtained; and if sulphat of soda be used, the result will be phosphat of soda.

Acid of Phosphorus. This acid, called also the *microscopic*

Phosphorus *crocoinic acid*, has already been described. See CHEMISTRY-Index at *Phosphoric Acid* (A). It has been discovered by Mr Scheele, that an acid capable of making phosphorus is producible from calcined bones or hartshorn and the vitriolic acid. The process for procuring this acid recommended by that gentleman was to dissolve the bones in nitrous acid; afterwards to precipitate the earth by means of the vitriolic acid; to filter and evaporate the liquor to dryness; and, after driving off the nitrous acid, the phosphoric acid remains. This process, however, is expensive on account of the waste of nitrous acid; and is likewise very inconvenient, because a great deal of the earthy matter continues dissolved even after the vitriolic acid is poured in; and therefore the phosphoric acid is never to be obtained pure: for which reason the following process is preferable.

Take of calcined bones or hartshorn, one pound; oil of vitriol, 14 ounces. Let the bones be reduced to fine powder; then pour on the acid undiluted, and rub both together till they are as accurately mixed as possible. Having let them remain for some hours in this situation, pour on as much water, stirring and dissolving the lumps, into which the mass will now be concentered, till it is all equally distributed through the liquid, and has the consistence of thick gruel. Let it remain 24 hours, and then pour it into a canvas cloth in order to let the liquor drain from it. This is a very tedious operation, as fresh water must continually be pouring on till all the saline matter is washed off. When this is done, pour into the liquid a quantity of caustic volatile alkali, which will occasion a copious precipitation; for the earth of bones is much less strongly attracted by acids than even the caustic volatile alkali. The liquid being now filtered a second time, which will be done with sufficient ease, and afterwards evaporated, there remains a mass composed of phosphoric acid and vitriolic sal ammoniac. By increasing the fire, the latter is dissipated in vapour; and if the process has been successful, four ounces or more of pure phosphoric acid will remain.

With regard to the properties of this acid, it is not yet ascertained whether they are exactly the same with the microcoinic acid or not. Indeed, as far as yet appears, they seem to be different; and there are very strong reasons for supposing that the phosphoric acid thus produced is no other than the vitriolic altered by its combination with the earth of bones. See the article BONES.

Liquor of PHOSPHORUS. See CHEMISTRY, n° 2d 957. 1521.

PHOTINIANS, in ecclesiastical history, were a sect of heretics in the fourth century who denied the divinity of our Lord. They derive their name from *Photinus* their founder, who was bishop of Sirmium, and a disciple of Marcellus. Photinus published in the year 343 his notions respecting the Deity, which were repugnant both to the orthodox and Arian systems. He asserted, that Jesus Christ was born of the Holy Ghost and the Virgin Mary; that a certain divine emanation, which he called the *Word*, descended upon Him; and that because of the union of the divine word with his human nature, He was called the son of God, and even God himself; and that the Holy Ghost was not a person, but merely a celestial virtue proceeding from the Deity. Both parties condemned the bishop in the councils of Antioch and Milan, held in the years 345 and 347. He was condemned also by the council at Sirmium in 351, and was afterwards degraded from the episcopal dignity, and at last died in exile in the year 372 or 375. His opinions were afterwards revived by Socinus.

PHOTIUS, patriarch of Constantinople, was one of the finest geniuses of his time, and his merit raised him to the patriarchate; for Bardas having driven Ignatius from the see, Photius was consecrated by Asbestos in 859. He condemned Ignatius in a synod, whereupon the pope excommunicated him, and he, to balance the account, anathematized the pope. Basilus of Macedon, the emperor whom Photius had reproved for the murder of Michael, the late emperor, expelled him, and restored Ignatius; but afterwards re-established Photius, upon Ignatius's death, in 878. At last, being wrongfully accused of a conspiracy against the person of Leo the Philosopher, the son and successor to Basilus, he was expelled by him in 886, and is supposed to have died soon after. He wrote a *Bibliotheca*, which contains an examen of 280 authors: we have also 253 epistles of his; the *Nomocanon* under 14 titles; an abridgment of the acts of several councils, &c. This great man was born in Constantinople, and was descended from a very illustrious and noble family. His natural abilities were very great, and he cultivated them with the greatest assiduity. There was no branch of literature, whether sacred or profane, and scarcely any art or science, in which he was not deeply versed. Indeed he appears to have been by far the greatest man of the age in which he lived; and was so intimately concerned in the chief transactions of it, that ecclesiastical writers have on that account called it *Seculum Photianum*. He was first raised to the chief dignities of the empire, being made principal secretary of state, captain

Photinians,
Photius.

(A) See particularly n° 904. In addition to what has been already said on the acid of phosphorus, we may just observe, that M. Pelletier has a memoir on this subject in the 14th volume of the *Chemical Annals*. This philosopher's method of preparing the phosphorous acid differs little from that which was some years ago proposed by M. Sage, and which, we believe, is now pretty generally known. The principal alterations made by the author of the present memoir consist in his putting each stick of phosphorus into a glass pipe, the lower part of which is shaped like a funnel terminating in a very small opening; and in covering the apparatus with a tubulated receiver, which he can open at pleasure. By these means he can dissolve a greater quantity of phosphorus without danger of an explosion. His method of converting the phosphorus into the phosphoric acid, by the nitric or the oxygenated muriatic acid, is the same with that discovered by M. Lavoisier, which is described in his *Elements of Chemistry*.

Phraates captain of the guards, and a senator. In all these stations he acquitted himself with a distinction suitable to his great abilities; for he was a refined statesman, as well as a profound scholar. His rise to the patriarchate was very quick; for when he was chosen to that office he was only a layman: but that he might be as it were gradually raised to that dignity, he was made monk the first day, reader the next, and the following days sub-deacon, deacon, and priest. So that in the space of six days he attained to the highest office in the church. On the whole, however his ardent love of glory and unbounded ambition made him commit excesses which rendered him a scourge to those about him.

Fabricius calls this *Bibliotheca* or library, *non liber, sed insignis thesaurus*, "not a book, but an illustrious treasure," in which are contained many curious things relating to authors, and many fragments of works which are no where else to be found. It was brought to light by Andreas Schottus, and communicated by him to David Hoefchelius, who caused it to be printed in 1601. Schottus, considering the great utility of this work, translated it into Latin, and printed his translation alone in 1606. The Greek text, together with the translation, were afterwards printed at Geneva in 1611. The last edition of this work, the largest, and the fairest, was printed at Rouen in 1653, folio.

PHRAATES, or **PHRAHATES**. There were four kings of this name in Parthia. See **PARTHIA**.

PHRASE, in grammar, an elegant turn or manner of speech, peculiarly belonging to this or that occasion, this or that art, or this or that language. Thus we say, an Italian *phrase*, an eastern *phrase*, a poetical *phrase*, a rhetorical *phrase*.

PHRASE is sometimes also used for a short sentence or small set or circuit of words constructed together. In this sense, Father Buffier divides phrases into complete and incomplete.

Phrases are *complete* where there is a noun and a verb, each in its proper function; *i. e.* where the noun expresses a subject, and the verb the thing affirmed of it.

Incomplete phrases are those where the noun and the verb together only do the office of a noun; consisting of several words without affirming anything, and which might be expressed in a single word. Thus, *that which is true*, is an incomplete phrase, which might be expressed in one word, *truth*; as, *that which is true satisfies the mind*, *i. e.* *truth satisfies the mind*.

PHRASEOLOGY, a collection of the phrases or elegant expressions in any language. See **PHRASE**.

PHREATIS, or **PHREATIUM**, in Grecian antiquity, was a court belonging to the civil government of Athens, situated upon the sea-shore, in the Piræus. The name is derived from *πρωτη φρεατις*, because it stood in a *pit*; or, as others suppose, from the hero *Phreatis*. This court heard such causes as concerned persons who had fled out of their own country for murder, or those that fled for involuntary murder, and who had afterwards committed a deliberate and wilful murder. The first who was tried in this place was Teucer, on a groundless suspicion that he had been accessory to the death of Ajax. The accused was not allowed to come to land, or so much as to cast anchor, but plead-

ed his cause in his bark; and if found guilty, was committed to the mercy of the winds and waves, or, as some say, suffered their condign punishment; if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelvemonth's banishment for the former. See Potter's *Gr. Antiq.* vol. i. p. 111.

PHRENETIC, a term used to denote those, who, without being absolutely mad, are subject to such strong fancies of imagination as in some measure pervert their judgment, and cause them to act in a way different from the more rational part of mankind.

PHRENITIS, the same with **PHRENSY**; an inflammation of the meninges of the brain, attended with an acute fever and delirium. See **MEDICINE**, n^o 176; also an account of a strange degree of phrenzy which attacked Charles VI. of France in the article **FRANCE**, n^o 88, 90.

PHRYGANEA is a genus of insects, of which Barbut gives the following characters. "The mouth is without teeth, but furnished with four palpi: the stemmata are three in number: the antennæ are filiform, and longer than the thorax. The wings are incumbent; the under ones are folded."

The same author informs us, that the genus is divided into two sections: the first of which is characterized, by having two truncated setæ at the extremity of the abdomen, resembling the beard of an ear of corn; while the second has the abdomen simple, or without appendices. The tarsi of the feet of the first family consist of three articulations; those of the second are composed of five. The wings of this section decline from the inner margin towards the sides, so as to resemble the ridge of a house, and are curved, or turn upwards at their extremity. "This insect (says Mr Barbut), before it becomes an inhabitant of the air, has lived under-water, lodged in a kind of tube or sheath, the inward texture of which is silk; outwardly covered with sand, straws, bits of wood, shells, &c. When the hexapod worm is about to change to a chrysalis, he stops up the opening of his tube with threads of a loose texture, through which the water makes its way, but prevents the approach of voracious insects. The chrysalis is covered with a thin gauze, through which the new form of the insect is easily discerned. The phryganea, on the point of changing its element, rises to the surface of the water, leaves its tube, rises into the air, and enjoys the sweets of the country, flutters upon flowers and trees, but is soon called away to the water side to deposit its eggs; whence proceeds its posterity. These aquatic larvæ are often found in stagnating waters, where they wrap themselves up in the water-lentil, cut out into regular squares, and fitted one to another. Trouts are very greedy of these larvæ; which is the reason, that in some countries, after stripping them of their coats, they make use of them for fishing-baits."

There are a variety of different species of the phryganea; but except the phryganea bicauda and striata, they do not materially differ from one another, except in size and colour. The bicauda is of a deep dark-brown colour; having a single yellow longitudinal band running across the head and thorax. The legs are of a brown colour, as are the antennæ; which are also long and filiform. Two brown threads, almost as

Phrenetic
||
Phryganea.

Phrygia. long as the antennæ, terminate the abdomen. The wings, which are about a third longer than the body; are veined with brown fibres, are narrow at the top, broad below, and are as it were stuck upon the body; which they infold, crossing one over the other. This insect, which is met with on the banks of rivers and standing-waters, carries its eggs in a cluster at its abdomen, like some spiders.

The *striata* is a large species, of a dun colour, except the eyes, which are black, and has a considerable resemblance to the *phalena* in the carriage of its wings. The antennæ are as long as the body, and are borne straight forward. The wings are a third larger than the body, having veins of a colour rather deeper than the rest. The feet are large, long, and somewhat finny. Mr Yeats tells us, that the *perlæ* of Geoffroy, and *phryganææ* of Linnæus, do not differ generically. It appears, however, from Yeats's experiments, that the *phryganææ* remain longer in the chrysalis than the *perlæ*.

The lesser *phryganææ* very much resemble the *tineæ*; but, upon examining them with a glass, the former will be found to be covered with small hairs instead of the scales which adorn the wings of the latter.

PHRYGIA, a country in Asia. From whence it derived its name is not certain: some say it was from the river Phryx (now Sarabat), which divides Phrygia from Caria, and empties itself into the Hermus; others from Phrygia, the daughter of Afopus and Europa. The Greek writers tell us, that the country took its name from the inhabitants, and these from the town of Brygium in Macedonia, from whence they first passed into Asia, and gave the name of *Phyrgia* or *Brygia* to the country where they settled. Bochart is of opinion that this tract was called Phrygia from the Greek verb *φρυγαν* "to burn or parch:" which, according to him, is a translation of its Hebrew name, derived from a verb of the same signification.

No less various are the opinions of authors as to the exact boundaries of this country; an uncertainty which gave rise to an observation made by Strabo, viz. that the Phrygians and Mysians had distinct boundaries; but that it was scarce possible to ascertain them. The same writer adds, that the Trojans, Mysians, and Lydians, are, by the poets, all blended under the common name of Phrygians, which Claudian extends to the Pisdians, Bithynians, and Ionians. Phrygia Proper, according to Ptolemy, whom we choose to follow, was bounded on the north by Pontus and Bithynia; on the west by Mylia, Troas, the Ægean Sea, Lydia, Mæonia, and Caria; on the south by Lycia; on the east by Pamphylia and Galatia. It lies between the 37th and 41st degrees of north latitude, extending in longitude from 56 to 62 degrees. The inhabitants of this country, mentioned by Ptolemy, are the Lycæones and Anthemisii, towards Lycia; and Moccadeliis or Moccadine, the Cyddelæ or Cydidæes towards Bithynia; and between these the Peltini or Spelini, the Moxiani, Phylæceses, and Hierapolitæ. To these we may add the *De-recyentes* mentioned by Strabo.

Phrygia is commonly divided into the Greater and Lesser Phrygia, called also Troas. But this division

did not take place till Troas was subdued by the Phrygians; and hence it is more considered by some Roman writers as a part of Phrygia, than Bithynia, Cappadocia, or any other of the adjacent provinces. In after ages, the Greater Phrygia was divided into two districts or governments; one called Phrygia Pacatiana, from Pacatianus, who, under Constantine, bore the great office of the præfectus prætorio of the East; the other Phrygia Salutaris, from some miraculous cures supposed to have been performed there by the archangel Michael.

This country, and indeed all Asia Minor, as lying in the fifth and sixth northern climates, was in ancient times greatly celebrated for its fertility. It abounded in all sorts of grain; being, for the most part, a plain country covered with a deep rich soil, and plentifully watered by small rivers. It was in some parts productive of bitumen and other combustible substances. It was well stocked with cattle, having large plains and pasture grounds. The air was anciently deemed most pure and wholesome, though it is now in some parts thought extremely gross, great part of the country lying uncultivated.

In Phrygia Major were anciently several cities of great celebrity; such as *AFANEÆ*, *LAODICEÆ*, *HIERAPOLIS*, *Gordium*, &c.—There were also some famous rivers; such as *Marsyas*, *Mæander*, &c. The *Mæander* is now called *Madre* or *Mindre*, and was much celebrated by the ancients for its windings and turnings; from whence all such windings and turnings have been denominated *mæanders*.

The Phrygians accounted themselves the most ancient people in the world. Their origin, however, is extremely dark and uncertain. Josephus and St Jerome say, they were descended from *togarmah*; one of Gomer's sons; and that they were known to the Hebrews under the name of *Tigrammanes*. The Heathen authors derive them from the Brygians, a people of Macedonia. But this is but mere conjecture; and it is a conjecture totally unsupported, except by the similarity of names. Bochart thinks that the Phrygians were the offspring of Gomer the eldest son of Japhet; the word Phrygia being the Greek translation of his name. Josephus makes Gomer the father of the Galatians; but he, by the Galatians must necessarily mean the Phrygians inhabiting that part of Phrygia which the Galatians had made themselves masters of; the descendants of Gomer being placed by Ezekiel northward of Judea, near *Togarmah* (which Bochart takes to be Cappadocia), long before the Gauls passed over into Asia. We are willing to let Gomer enjoy the fine country which Bochart is pleased to give him, and allow him the honour of being the progenitor of the Phrygians, since we know no other person on whom it can be conferred with any degree of probability.

The ancient Phrygians are described as superstitious, voluptuous, and effeminate, without any prudence or forecast, and of such a servile temper, that nothing but stripes and ill usage could make them comply with their duty; which gave rise to several trite and well known proverbs (A). They are said to have been the first inventors of divination by the singing, flying, and feeding

Ancient Univ. Hist. vol. iii. p. 441, &c.

(A) "Phryges fero sapiunt, Phryx verberatus melior, Phryx non minus quam Spyntharus, &c.:" which proverbs

Phrygia. feeding of birds. Their music, commonly called the *Phrygian mood*, is alleged by some as an argument of their effeminacy.

Their government was certainly monarchical; for all Phrygia was during the reigns of some kings, subject to one prince. Ninnæus, Midas, Manis, Gordius, and his descendants, were undoubtedly sovereigns of all Phrygia. But sometime before the Trojan war, we find this country divided into several petty kingdoms, and read of divers princes reigning at the same time. Apollodorus mentions a king of Phrygia contemporary with Ilus king of Troy. Cedrenus and others speak of one Teuthrans king of a small country in Phrygia, whose territories were ravaged by Ajax, himself slain in single combat, his royal seat laid in ashes, and his daughter, by name Tecmessa, carried away captive by the conqueror. Homer makes mention of Phoreys and Ascanius, both princes and leaders of the Phrygian auxiliaries that came to the relief of Troy. Tantalus was king of Sipylus only, and its district; a prince no less famous for his great wealth, than infamous for his covetousness and other detestable vices. That Phrygia was subdued either by Ninus, as Diodorus Siculus informs us, or by the Amazons, as we read in Suidas, is not sufficiently warranted. Most authors that speak of Gordius tell us, that the Phrygians having sent to consult an oracle in order to know how they might put an end to the intestine broils which rent their country into many factions and parties, received for answer, that the most effectual means to deliver themselves and their country from the calamities they groaned under, was to commit the government to a king. This advice they followed accordingly, and placed Gordius on the throne.

As to their commerce, all we can say is, that Apamea was the chief emporium of all Asia Minor.—Thither resorted merchants and traders from all parts of Greece, Italy, and the neighbouring islands. Besides, we know from Syncellus, that the Phrygians were for some time masters of the sea; and none but trading nations ever prevailed on that element. The country produced many choice and useful commodities which afforded considerable exports. They had a safe coast, convenient harbours, and whatever may incline us to think that they carried on a considerable trade. But as most of the Phrygian records are lost, we will not dwell on conjectures so difficult to be ascertained.

We have no set form of their laws; and as to their learning, since we are told that for some time they enjoyed the sovereignty of the sea, we may at least allow them a competent skill in geography, geometry, and astronomy; and add to these, from what we

VOL. XIV.

have said above, a more than ordinary knowledge of music.

Some have been of opinion that the Phrygian language bore a great resemblance to the Greek; but the contrary is manifest from the few Phrygian words which have been transmitted to us and carefully collected by Bochart and Rudbeckius. To these we may add the authority of Strabo, who, after attempting to derive the name of a Phrygian city from the Greek, concludes, that it is a difficult matter to discover any similitude between the barbarous words of the Phrygian language and the Greek. The Phrygian tongue, after the experiment made by Psammethichus king of Egypt, was looked upon by the Egyptians as the most ancient language of the world. But other nations, particularly the Scythians, refused to submit to their opinion, as founded on an argument of no real weight. "As the two children (say they) had never heard the voice of any human creature, the word *bec*, or *bakkos*, the first they uttered, was only an imitation of the goats that had suckled them, and happened to be a Phrygian word signifying *bread* (B).

We have already said, that the Phrygians were superstitious; their idols were consequently very numerous. The chief of these was Cybele, who went by a variety of names. (See *CYBELE*.) They also worshipped Bacchus under the name of *Sabazios*; and his priests they called *Saboi*.

The history of their kings is dark and uncertain, and the dates of their several reigns and actions cannot now be fixed; we shall refer such of our readers, therefore, as wish to know what is certain respecting them, to the Ancient Universal History, already quoted more than once in the present article. See also *GORDIUS*, *MIDAS*, &c. For Phrygia Minor, see *TROY*.

PHRYGIAN STONE, in natural history, is the name of a stone described by the ancients, and used by them in dying; perhaps from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers. It was light and spongy, resembling a pumice; and the whitest and lightest were reckoned the best. Pliny gives an account of the method of preparing it for the purpose of dying, which was by moistening it with urine, and then heating it red hot, and suffering it to cool.—This calcination was repeated three times, and the stone was then fit for use. Dioscorides recommends it in medicine after burning; he says it was drying and astringent.

PHRYGIANS, a Christian sect. See *CATECHRYGIANS* and *MONTANIST*.

PHRYNE, was a famous prostitute who flourished at Athens about 328 years before the Christian era. She was mistress of Praxiteles, who drew her picture.

4 L

which

proverbs intimate their servile temper; and show that they were more fit to bewail misfortunes in an unmanly manner, than to prevent them by proper measures. Their music, too, was suited to their effeminate temper. The Doric mood was a kind of grave and solid music; the Lydian a doleful and lamentable harmony; but the Phrygian chiefly calculated to effeminate and enervate the mind. But this character is contradicted by others.

(B) Goropius Becanus makes use of the same argument, to prove that the High-Dutch is the original or mother-tongue of the world, because the word *baker* in that language signifies "a baker."

Phrygia
||
Phryne.

Phryxus which was one of his best pieces, and was placed in the temple of Apollo at Delphi. We are told that Apelles painted his Venus Anadyomene after he had seen Phryne on the sea-shore naked, and with dishevelled hair. Phryne became so very rich by the liberality of her lovers, that she offered to rebuild Thebes at her own expence, which Alexander had destroyed, provided this inscription was placed on the walls: *Alexander, diruit sed meretrix Phryne refecit*; which was refused. See *Plin.* 34. c. 8.—There was another of the same name who was accused of impiety. When she found that she was going to be condemned, she unveiled her bosom, which so influenced her judges that she was immediately acquitted.

PHRYNICUS, a general of Samos, who endeavoured to betray his country, &c.—A flatterer at Athens.—A tragic poet of Athens, disciple to Theſpis. He was the first who introduced a female character on the stage.

PHRYNIS was a musician of Mitylene. He was the first who obtained a musical prize at the Panathenæa at Athens. He added two strings to the lyre, which had always been used with seven by all his predecessors. He flourished about 438 years before the Christian era. We are told that he was originally a cook at the house of Hiero king of Sicily.—There was another of the same name, a writer in the reign of Commodus, who made a collection, in 36 books, of phrases and sentences from the best Greek authors, &c.

PHRYXUS (fab. hist.), was a son of Athamas king of Thebes, by Nephele. When his mother was repudiated, he was persecuted with the most inveterate fury by his step-mother Ino, because he was to sit on the throne of Athamas, in preference to the children of a second wife. His mother apprized him of Ino's intentions upon his life; or, according to others, his preceptor; and the better to make his escape, he secured part of his father's treasures, and privately left Bœotia with his sister Helle, to go to their friend and relation Æetes king of Colchis. They embarked on board a ship, or, as we are informed by the fabulous account of the poets and mythologists, they mounted on the back of a ram, whose fleece was of gold, and proceeded on their journey through the air. The height to which they were carried made Helle giddy, and she fell into the sea. Phryxus gave his sister a decent burial on the sea-shore, and after he had called the place *Helleſpont* from her name, he continued his flight, and arrived safe in the kingdom of Æetes where he offered the Ram on the altars of Mars. The king received him with great tenderness, and gave him Chalciopé his daughter in marriage. She had by him Phrontis Melas, Argos Cylindrus, whom some call *Cyturus*. He was afterwards murdered by his father-in-law, who envied him the possession of the golden fleece; and Chalciopé, to prevent her children from sharing their father's fate, sent them privately from Colchis to Bœotia, as nothing was to be dreaded there from the jealousy or resentment of Ino, who was then dead. The fable of the flight of Phryxus to Colchis on a ram has been explained by some, who observe, that the ship on which he embarked was either called by that name, or carried on her prow a figure of that

animal. The fleece of gold is accounted for, by observing that Phryxus carried away immense treasures from Thebes. Phryxus was placed among the constellations of heaven after death. The ram which carried him to Asia is said to have been the fruit of Neptune's amour with Theophrane the daughter of Alcis. This ram the gods had given to Athamas in order to reward his piety and religious life; and Nephele procured it for her children, just as they were going to be sacrificed to the jealousy of Ino. Phryxus's murder was some time after amply revenged by the Greeks; it having occasioned the famous expedition atchieved under Jason and many of the princes of Greece, which had for its object the recovery of the golden fleece, and the punishment of the king of Colchis for his cruelty to the son of Athamas.

PHTHIRIASIS, the LOUSY EVIL from *φθειρα*, "a louse." It is a lousy distemper; children are frequently its subjects, and adults are sometimes troubled with it. The increase of lice, when in a warm moist situation, is very great; but a cold and dry one soon destroys them. On the human body four kinds of lice are distinguished: 1. The *pediculi*, so called because they are more troublesome with their feet than by their bite. These are in the heads of children, especially if sore or scabby; and often in those of adults, if they are slothful and nasty. 2. Crab-lice, see *CRAB LICE*. 3. Body lice; these infest the body, and breed in the clothes of the nasty and slothful. 4. A sort which breed under the cuticle, and are found in the hands and feet: they are of a round form, and so minute as often to escape the sight: by creeping under the scarf-skin they cause an intolerable itching; and when the skin bursts where they lodge, clutters of them are found there. See *ACARUS*.

A good diet and cleanliness conduce much to the destruction of lice. When they are in the head, comb it every day; and, after each combing, sprinkle the pulv. sem. *staph. agr.* or *coccul.* Ind. among the hairs every night and confine it with a tight cap.

Codrochius, in his treatise on lice, says, that the powdered *coc.* Ind. exceeds all other means; and that it may be mixed in the pulp of apple, or in lard, and applied every night to the hair. Some writers assert that if the pulv. *cort. rad. saffaffr.* is sprinkled on the head, and confined with a handkerchief, it destroys the lice in one night.

The body-lice are destroyed by any bitter, sour, salt, or mercurial medicine, if applied to the skin.

The black soap, and the flowers called *cardamine* or *lady's-smock*, are said to be specifics in all cases of lice on the human body.

PHTHISIS, a species of consumption, occasioned by an ulcer in the lungs. See *MEDICINE*, n^o 237, &c.

Since our article *MEDICINE* was published, Dr Beddoes has suggested * a new theory of phthisis, founded on the prevailing pneumatic doctrine in chemistry. Thinking that much cannot be gained by adhering to established principles and modes of practice, and being unawed by any pretensions to success from experience, he enters into the province of speculation. He fixes on the effect of pregnancy in suspending the progress of phthisis, as a fact which, by its mode of operation, might

Phthiriasis,
Phthisis.

* Observations on the Nature and Cure of Calculus, Sex-feurvy, &c.

Phthisis. might suggest a method of diminishing the hæmorrhage occasioned by this distemper. We shall give his explanation of this interesting fact:

“The fœtus has its blood oxygenated by the blood of the mother through the placenta. During pregnancy there seems to be no provision for the reception of an unusual quantity of oxygen. On the contrary, in consequence of the impeded action of the diaphragm, less and less should be continually taken in by the lungs. If, therefore, a somewhat diminished proportion of oxygen be the effect of pregnancy, may not this be the way in which it arrests the progress of phthisis? and if so, is there not an excess of oxygen in the system of consumptive persons? and may we not, by pursuing this idea, discover a cure for this fatal disorder?”

Dr Beddoes thinks, that this supposition is countenanced by the deficiency of oxygen in the blood of pregnant women, of asthmatic patients, and of those who labour under sea-scurvy; and by the superabundance of it in the blood of phthisical persons, indicated by its colour, as well as by the aggravation of the symptoms of consumption by breathing oxygen air, and by the relief from inspiring atmospheric air mixed with carbonic acid air; and, lastly, from the small proportion of deaths among sea-faring people. Supposing acids to act by decomposition, their alleged effects in producing consumption are consistent with the author's doctrine, as well as the emaciation preceding and accompanying phthisis. From these facts, Dr Beddoes concludes, that “1. The phthisical inflammation may so alter the structure of the lungs, as to cause them to transmit a more than ordinary portion of oxygen to the blood; or, 2. Some unknown cause having enabled them to transmit, or the blood itself to attract, more oxygen, an inflammation of the lungs might ensue.”

From these principles, the Doctor thinks himself justified in proposing, in a disease which is incurable by present modes of practice, to diminish the supply of oxygen by the two channels through which it is introduced; namely, through the lungs, by lowering the atmospheric air with azotic or hydrogen air; and through the stomach, by giving such nourishment as contains a small portion of oxygen.

Such is Dr Beddoes's theory of consumption; on which the following remark has been made by a critic* who possesses an equal degree of candour and judgment. It is assumed by Dr Beddoes, that the blood of pregnant women has a diminished proportion of oxygen: but pregnant women have the same circumscribed spot of florid red in their countenances which is apparent in hectic. If, then, the presence of this colour be sufficient to prove an excess of oxygen in the one case, it must have the same weight in the other. Another question is, whether less oxygen be really taken in by the lungs during pregnancy? For although the diaphragm be impeded in the freedom of its action, the frequency of breathing is proportionally increased.—A third circumstance which demands attention is, in what degree the fœtus has its blood oxygenated by the blood of the mother through the placenta. It appears highly probable, that the fetal blood receives a very trifling supply of oxygen from the blood of the mother; that the fetal heart

contains only a small portion of blood, which has been conveyed to the placenta; and that the blood in the heart and arteries of the fœtus is not florid.—For many ingenious arguments on this subject, we may refer to Mr Coleman's Dissertation on suspended Respiration.—Leaving these things to Dr Beddoes's consideration, we will present our readers with his concluding remarks on this subject:

“The more you reflect, the more you will be convinced, that nothing would so much contribute to rescue the art of medicine from its present helpless condition, as the discovery of the means of regulating the constitution of the atmosphere. It would be no less desirable to have a convenient method of reducing the oxygen to 18 or 20 in 100, than of increasing it in any proportion. The influence of the air we breathe is as wide as the diffusion of the blood. The minutest portions of the organs of motion, sense, and thought, must be affected by any considerable change in this fluid. Whether it be that the brain must be washed by streams of arterial blood, or that the action of every organ is a stimulus to the system in general, and consequently to every other organ in particular; it is certain, that when the access of oxygen is cut off from the lungs, the functions of the brain cease: perhaps there may be a mixture of azotic and oxygen airs, more favourable to the intellectual faculties than that which is found in the atmosphere; and hence chemistry be enabled to exalt the powers of future poets and philosophers. That diseases of excitement on the one hand, and debility on the other, might be cured almost solely by a proper air, one can hardly doubt, as well as several disorders at present highly dangerous or desperate, which one cannot, upon the faith of any obvious phenomena, refer to either head. The materia medica might, therefore, undergo a still greater reduction than it has lately undergone, in consequence of the purification of medicine from its grosser absurdities; and hence the treatment of diseases be at once rendered infinitely more pleasant and more efficacious.”

Our author, in a subsequent publication † gives an account of his treating with success several cases of phthisis according to the principles of this theory. After distinguishing consumptions into two kinds, the florid and the pituitous or catarrhal, he observes, “that the system may be as variously affected by means of the lungs as of the stomach: that it is impossible to doubt that we are nourished by the lungs as truly as by the stomach: and what we take in at the former entrance, becomes, like our food, a part of the substance of our solids as well as of our fluids. By the lungs we can also introduce effectual alteratives of the blood, and by consequence of all the parts nourished by the blood.”

He then acquaints us more particularly with the apparatus requisite for the practice proposed. 1st, It should be able to furnish azotic, hydrogen, carbonic, and oxygen airs: our author having, as he says, “no intention to confine himself to one incurable disorder. 2dly, The reservoirs should be large, that the patients may be supplied with any quantity that their symptoms may require: and, 3dly, It is necessary to be able to mix these airs with one another, as well as with atmospheric air, in any proportion.” These objects, we

* Monthly Rev. Nov. 1793, p. 273.

† A Letter to Erasmus Darwin, M. D.

Phul
Phyllis.

are told, have been completely attained by a construction not very unlike to that employed in the gazometers of M. Lavoisier and Dr Van Marum.

PHUL, or PUL, king of Assyria, is by some historians said to be Ninus under another name, and the first founder of that monarchy: A renowned warrior. He invaded Israel in the reign of Manahem, who became tributary to him, and paid him 1000 talents of silver for a peace. Flourished 771 B. C.

PHUT, or PHUTH, the third son of Ham (Gen. x. 6.) Calmet is of opinion, that Phut peopled either the canton of Phtemlu, Phtemphuti, or Phtemuti, set down in Pliny and Ptolemy, whose capital was Thara in Lower Egypt, inclining towards Lybia; or the canton called Phtenotes, of which Buthus was the capital. The prophets often speak of Phut. In the time of Jeremiah, Phut was under the obedience of Necho king of Egypt. Nahum (iii. 9.) reckons up his people in the number of those who ought to have come to the assistance of No-ammon or Diospolis.

PHYLACTERY, in the general, was a name given by the ancients to all kinds of charms, spells, or characters, which they wore about them, as amulets, to preserve them from dangers or diseases.

PHYLACTERY particularly denoted a slip of parchment, wherein was written some text of Holy Scripture, particularly of the decalogue, which the more devout people among the Jews wore on the forehead, the breast, or the neck, as a mark of their religion.

The primitive Christians also gave the name *phylacteries* to the cases wherein they inclosed the relics of their dead.

Phylacteries are often mentioned in the New Testament, and appear to have been very common among the Pharisees in our Lord's time.

PHYLICA, BASTARD ALATERNUS; a genus of the monogynia order, belonging to the pentandria class of plants. There are six species, of which three are kept in the gardens of Britain; but by reason of their being natives of warm climates, they require to be kept in pots, and housed in winter. They are all shrubby plants, rising from three to five or six feet high, and adorned with beautiful clusters of white flowers. They are propagated by cuttings.

PHYLLANTHUS, SEA-SIDE LAUREL; a genus of the triandria order, belonging to the monœcia class of plants. There are six species, all of them natives of warm climates; and rise from 12 or 14 feet to the height of middling trees. They are tender, and cannot be propagated in cold countries without artificial heat.

PHYLLIS (fab. hist.), was a daughter of Sithon, or, according to others, of Lycurgus king of Thrace, who received Demophoon the son of Theseus; who, at his return from the Trojan war, had stopped on her coasts. She became enamoured of him, and did not find him insensible to her passion. After some months of mutual tenderness and affection, Demophoon set sail for Athens, where his domestic affairs recalled him. He promised faithfully to return as soon as a month was expired; but either his dislike for Phyllis, or the irreparable situation of his affairs, obliged him to violate his engagement: and the queen grown desperate on account of his absence, hanged herself, or, according to others, threw herself down a pre-

cipice into the sea and perished. Her friends raised a tomb over her body, where there grew up certain trees, whose leaves, at a particular season of the year, suddenly became wet as if shedding tears for the death of Phyllis. According to an old tradition mentioned by Servius, Virgil's commentator, Phyllis was changed by the gods into an almond tree, which is called *phyllis* by the Greeks. Some days after this metamorphosis, Demophoon revisited Thrace; and when he heard of the fate of Phyllis, he ran and clasped the tree, which, though at that time stripped of its leaves, suddenly shot forth, and blossomed as if still sensible of tenderness and love. The absence of Demophoon from the house of Phyllis has given rise to a beautiful epistle of Ovid, supposed to have been written by the Thracian queen about the fourth month after her lover's departure.—A country woman introduced in Virgil's eclogues.—The nurse of the emperor Domitian.—A country of Thrace near mount Pangæus.

PHYSALIS, the WINTER CHERRY; a genus of the monogynia order, belonging to the pentandria class of plants. There are 16 species; of which the most remarkable is the alkekengi, or common winter-cherry. This grows naturally in Spain and Italy. The roots are perennial, and creep in the ground to a great distance if they are not confined. These, in the spring, shoot up many stalks, which rise to the height of a foot or more, garnished with leaves of various sorts; some of which are angular and obtuse, some oblong and sharp pointed, with long foot-stalks. The flowers are produced from the wings, standing upon slender foot-stalks; are of a white colour, and have but one petal. They are succeeded by round berries about the size of small cherries, inclosed in an inflated bladder, which turns red in autumn, when the top opens and discloses the red berry, which is soft, pulpy, and filled with flat kidney-shaped seeds. Soon after the fruit is ripe, the stalks decay to the root. The plant is easily propagated, either by seeds or parting the roots.

PHYSALUS. See SCOLOPENDRA.

PHYSETER, or SPERMACETI-FISH, in zoology, a genus belonging to the order of cete. There are four species; the most remarkable are,

1. The microps, or black-headed cachalot, with a long fin on the back, and the upper jaw considerably longer than the under one. A fish of this kind was cast ashore on Cramond isle, near Edinburgh, December 22. 1769; its length was 54 feet; the greatest circumference, which was just beyond the eyes, 30: the upper jaw was five feet longer than the lower, whose length was ten feet. The head was of a most enormous size, very thick, and above one-third the size of the fish: the end of the upper jaw was quite blunt, and near nine feet high: the spout-hole was placed near the end of it. The teeth were placed in the lower jaw, 23 on each side, all pointing outwards; in the upper jaw, opposite to them, were an equal number of cavities, in which the ends of the teeth lodged when the mouth was closed. One of the teeth measured eight inches long, the greatest circumference the same. It is hollow within-side for the depth of three inches, and the mouth of the cavity very wide: it is thickest at the bottom, and grows very small at the point, bending very much; but in some the flexure is more than in others. These, as well as the teeth of all

Physalis
Physeter.

Phyſeter. all other whales we have obſerved, are very hard, and cut like ivory. The eyes are very ſmall, and remote from the noſe. The pectoral fins were placed near the corners of the mouth, and were only three feet long: it had no other fin, only a large protuberance on the middle of the back. The tail was a little forked, and 14 feet from tip to tip. The penis ſeven feet and a half long. Linnæus informs us, that this ſpecies purſues and terrifies the porpoifes to ſuch a degree as often to drive them on ſhore.

2. The catodon, or round headed cachalot, with a fiſtula in the ſnout, and having no back-fin. Of this ſpecies, 102 of different ſizes were caſt aſhore at one time on one of the Orkney Iſles, the largeſt 24 feet in length. The head is round, the opening of the mouth ſmall. Sibbald ſays it has no ſpout hole, but only noſtrils: But Mr Pennant is of opinion, that the former being placed at the extremity of the noſe, has been miſtaken by him for the latter. Some teeth of this ſpecies are an inch and three quarters long, and in the largeſt part of the thickneſs of one's thumb. The top is quite flat, and marked with concentric lines; the bottom is more ſlender than the top, and pierced

with a ſmall orifice: inſtead of a back fin, there was a rough ſpace.

For the method of extracting the ſpermaceti from the bram of theſe creatures, ſee the article SPERMACEIN.

PHYSIC, or PHYSICK, the art of healing; properly called MEDICINE. The word is formed from the Greek φυσικ, "nature;" in regard medicine conſiſts principally in the obſervation of nature. See PHYSICS and MEDICINE.

PHYSICAL, ſomething belonging to, or really exiſting in, nature. In this ſenſe we ſay a physical point, in oppoſition to a mathematical one, which only exiſts in the imagination; a physical ſubſtance or body, in oppoſition to ſpirit, or metaphyſical ſubſtance, &c.

PHYSICIAN, a perſon who profeſſes medicine, or the art of healing diſeaſes. See MEDICINE.

PHYSICIANS, *College of, in London and Edinburgh.* See COLLEGE of Physicians.

PHYSICO-MATHEMATICS, includes thoſe branches of phyſic which, uniting obſervation and experiment to mathematical calculation, undertake to explain the phenomena of nature.

tics.

P H Y S I C S,

1
General
definition
of phyſics.

TAKEN in its moſt enlarged ſenſe, comprehends the whole ſtudy of nature; and NATURAL PHILOSOPHY is a term of the ſame extent: but ordinary language, and eſpecially in this country, employs both of theſe terms in a much narrower ſenſe, which it is proper in this place to determine with ſome precision.

2
A more
particular
explanation
of the term.

Under the article PHILOSOPHY, we gave a particular account of that view of nature in which the objects of our attention are conſidered as connected by cauſation; and we were at ſome pains to point out the manner in which this ſtudy may be ſucceſſfully cultivated. By a judicious employment of the means pointed out in that article, we diſcover that the objects of our contemplation compoſe an UNIVERSE, which conſiſts, not of a number of independent exiſtences ſolitary and detached from each other, but of a number of ſubſtances connected by a variety of relations and dependencies, ſo as to form a whole which may with great propriety be called the SYSTEM OF NATURE.

This aſſembling of the individual objects which compoſe the univerſe into one ſyſtem is by no means the work of a haſty and warm fancy, but is the reſult of ſober contemplation. The natural hiſtorian attempts in vain to deſcribe objects, by only informing us of their ſhape, colour, and other ſenſible qualities. He finds himſelf obliged, in deſcribing a piece of marble for inſtance, to tell us that it takes a fine poliſh; that it ſtrikes fire with ſteel; that it burns to quicklime; that it diſſolves in aquafortis, and is precipitated by alkalis; that with vitriolic acid it makes gypſum, &c. &c. &c. and thus it appears that even the deſcription of any thing, with the view of aſcertaining its ſpecific nature, and with the ſole purpoſe of diſcrimination, cannot be accompliſhed without

taking notice of its various relations to other things. But what do we mean by the nature of any thing? We are ignorant of its eſſence, or what makes it that thing and no other thing. We muſt content ourſelves with the diſcovery of its qualities or properties; and it is the aſſemblage of theſe which we call its nature. But this is very inaccurate. Theſe do not conſtitute its eſſence, but are the conſequences of it. Yet this is all we ſhall ever know of its nature. Now the term property is nothing but a name expreſſing ſome relations which the ſubſtance under conſideration has to other things. This is true of all ſuch terms. Gravity, elasticity, ſenſibility, gratitude, and the like, expreſs nothing but certain matters of fact, which may be obſerved reſpecting the object of our contemplation in different circumſtances of ſituation with regard to other things. Our diſtinct notions of individuals, therefore, imply their relations to other things.

Introduc-
tion.

The ſlighteſt obſervation of the univerſe ſhows an evident connection between all its parts in their various properties. All things on this earth are connected with each other by the laws of motion and of mind. We are connected with the whole of the ſolar ſyſtem by gravitation. If we extend our obſervations to the fixed ſtars, the connection ſeems to fail; but even here it may be obſerved. Their inconceivable diſtance, it is true, renders it impoſſible for us to obtain any extenſive information as to their nature. But theſe bodies are connected with the ſolar ſyſtem by the ſame neſs of the light which they emit with that emitted by our ſun or any thinning body. It moves with the ſame velocity, it conſiſts (in moſt of them at leaſt) of the ſame colours, and it is reflected, refracted, and inſected, according to the ſame laws.

3

5
Nature of
intention.

jects nearly in proportion to the interest we take in them. There is nothing in which we are so much interested as our fellow men; and one of the first steps that we make in our knowledge of nature, is an acquaintance with them. We learn their *distinctive* nature by attending to their *characteristic* appearances; that is, by observing their actions. We observe them continually producing, like ourselves, certain changes in the situation or condition of surrounding objects; and these changes are evidently directed to certain ends *which respect themselves*. Observing this subserviency of the effects which they produce to their own accommodation, we consider this adjustment of means to ends as the effect of an INTENTION, as we experience it to be in our own case, where we are conscious of this intention, and of these its effects. We therefore interpret those actions of other men, where we observe this adjustment of means to ends, as marks or signs of intention in them similar to our own. And thus a quality, or power, or faculty, is *supposed* in them *by means of its sign*, although the quality itself is not *immediately* cognizable by our senses. And as this intention in ourselves is accompanied by perception of external objects, knowledge of their properties, desire of good, aversion from evil, volition, and exertion, without all of which we could not or would not perform the actions which we daily perform, we *suppose* the same perception, knowledge, desire, aversion, volition, and exertion in them.

Thus, by the constitution of our mind, we consider the employment of means, by which ends terminating in the agent are gained, as the natural signs of design or intention. ART, therefore or the employment of means, is the natural sign of intention; and wherever we observe this adjustment of means to ends, we infer the agency of design.

A small acquaintance with the objects around us, obliges us to extend this inference to a great number of beings besides our fellow men, namely, to the whole animal creation: for in all we observe the same subserviency to the ends of the agent, in the changes which we find them continually producing in the objects around them. These changes are all adjusted to their own well being. In all such cases, therefore, we are forced, by the constitution of our own minds, to infer the existence of design or intention in these beings alio.

But in numberless changes produced by external objects on each other, we observe no such fitness in the effects, no such subserviency to the well being of the agent. In such cases, therefore, we make no such inference of thought or design.

6
All objects
divided in-
to thinking
and un-
thinking
beings.

Thus, then, is presented to our observation an important distinction, by which we arrange all external objects into two classes. The first resembles ourselves, in giving external marks of that thought or intention of which we are conscious; and we *suppose* in them the other properties which we discover in ourselves, but cannot *immediately* observe in them, viz. thought, perception, memory, foresight, and all that collection of faculties which we feel in ourselves, and which constitute the animal. The other class of objects exhibit no such appearances, and we make no such inference. And thus we divide the whole of external nature into the classes of THINKING and UN-THINKING beings.

Our first judgments about these classes will be very

inaccurate; and we will naturally ascribe the differences, which we do not very well understand, to the differences in organical structure, which we clearly observe. But when we have knocked down or perhaps smothered an animal, we find that it no longer gives the former marks of thought and intention, and that it now resembles the class of unthinking beings: And yet it still retains all that fitness of organical structure which it had before; it seems only to want the intention and the will. This obliges us to conclude that the distinction does not arise from a difference in organical structure, but from a distinct substance common to all thinking beings, but separable from their organical frame. To this substance we ascribe thought, intention, contrivance, and all that collection of faculties which we feel in ourselves. To this substance in ourselves we refer all sensations, pleasures, pains, remembrances, desires, purposes; and to this aggregate, however imperfectly understood, we give the name MIND. Our organical frame, which seems to be only the instrument of information and operation to the mind, we call *our body*.

As the animating principle is not, like our body, the immediate object of the senses, we naturally conceive it to be a substance essentially different from those which are the objects of our senses. The rudest people have shown a disposition to form this conclusion. Observing that animal life was connected with breathing, it was natural to imagine that breathing was living, and that breath was life. It is a remarkable fact, that in most languages the term for expressing *breath* is at least one of the terms for expressing the soul: רוח, *רוח*, *spiritus*, in the Hebrew, Greek, and Latin, express both; *gheist* or *ghost*, in the Teutonic, comes from *gheisen*, to "breathe or sigh;" *dücha* or *düha*, "the soul," in Slavonic, comes from *duchat*, "to breathe;" so in the Gaelic does *anal* come from *anam*; and the same relation is found between the two words in the Malay and other eastern languages. We believe that most persons can recollect some traces of this notion in their early conceptions of things; and many who do not consider themselves as uncultivated, believe that the soul quits the body *along with the last breath*. Among the Tartar nations hanging is considered with particular horror, on account of the ungraceful and filthy exit which the soul is obliged to make from the body.

But the observation of the same appearances of thought and intention in fishes and other animals which do not breathe, would soon show that this was but a rude conception. Very little refinement indeed is necessary to convince us that air or breath cannot be the substance which thinks, wishes, and designs; and that the properties of this substance, whatever it is, must be totally different from, and incompatible with, any thing that we know of the immediate objects of our senses.

Hence we are led to conclude that there are two kinds of substances in nature: One, which is the principle of sensation; and therefore *cannot* be the object of our senses, any more than light can be the object of the microscope. This substance alone can feel, think, desire, and propose, and is the object of *reflection alone*. The objects of our senses compose the other class, and therefore can have none of the other properties which are not cognoscible by the senses. These have all the

properties

Introduction. properties which our senses can discover; and we can have no evidence of their having any other, nor indeed any conception of their having them. This class is not confined to the unorganized masses of matter; for we see that the bodies of animals lose after death that organical form, and are assimilated to all the rest of unthinking beings. It has arisen from such views as this, that while all nations have agreed to call this class of objects by the name *body*, which originally expresses our organical frame, some nations, farther advanced in cultivation or refinement, have contrived an abstract term to express this general substance of which all inanimate beings are composed. Such a term we have in the words *materies*, &c.

11
The distinction between material and immaterial substances is very important.

Matter, then, is that substance which is immediately cognoscible by our senses. Whatever, therefore, is not thus immediately cognoscible by our senses is not material, and is expressed by a negative term, and called *immaterial*: hence it is that mind is said to be immaterial. It is of importance to keep in mind this distinction, merely grammatical. Little more is necessary for detecting the sophisms of Helvetius, Mirabeau, and other sages of the Gallic school, who have been anxious to remove the ties of moral and religious obligation by lowering our conceptions of our intellectual nature. It will also serve to show how hastily they have formed their opinions who have ascribed to the immediate agency of mind all those relations which are observed in the actions of bodies on each other at a distance. The connecting principles of such relations *e distante* (if there are any such), are not the immediate objects of our senses: they are therefore immaterial. But it does not follow that they are minds. There may be many immaterial substances which are not minds. We know nothing of any object whatever but by the observation of certain appearances, which suggest to our minds the existence and agency of its qualities or powers. Such phenomena are the natural signs of these qualities, and it is to those signs that we must always have recourse when we wish to conceive without ambiguity concerning them. What is the characteristic phenomenon of mind, or what is the *distinguishing* quality which brings it into view? It is *intention*: and it may be asserted with the utmost confidence, that we have no other mark by which mind is immediately suggested to us, or that would ever have made us suppose that there existed another mind besides our own. The *phenomenon* by which this quality is suggested to us is *art*, or the employment of means to gain ends; and the mark of art is the supposed conduciveness of these ends to the well-being of the agent. Where this train is not observed, design or intention is never thought of; and therefore where intention is not perceived in any immaterial substance, if any such has ever been observed, it is an abuse of language to call it mind. We do not think that even perception and intelligence intitle us to give the name *mind* to the substance in which they are inherent, because it is from marks of intention alone that we infer the existence of mind; and although these must be accompanied with perception and intelligence, it does not follow that the substance which can perceive and understand must also desire and propose. However difficult we may find it to separate them, they are evidently separable in imagination. And let not this

assertion be too hastily objected to; for the separation *has been made* by persons most eminent for their knowledge and discernment. When Leibnitz ascribed to his *MONADES*, or what we call the ultimate *ATOMS* of matter, a perception of their situation in the universe, and a motion precisely suited to this perception, he was the farthest in the world from supposing them animated or endowed with minds. It is true indeed that others, who think and call themselves philosophers, are much more liberal in their application of this term. A modern author of great metaphysical eminence says, "I call that *mind* which moves, and that *body* which is moved." This class of philosophers assert that no motion whatever is begun except by the agency of an animating principle, which (after Aristotle) they call *Nature*, and which has in these days been exalted to the rank of a god. All this jargon (for it is nothing else) has arisen from the puzzle in which naturalists think themselves involved in attempting to explain the production of motion in a body at a distance from that body which is conceived as the cause of this motion. After having been reluctantly obliged, by the reasonings of Newton, to abandon their methods of explaining such phenomena by the impulses of an intervening fluid, nothing seemed left but the assertion that these motions were produced by minds, as in the case of our own exertions. These explanations (if they deserve the name) cannot be objected to in any other way than as an abuse of language, and as the introduction of an unmeaning jargon. We have, and can have, no notion of mind different from those of our own minds; and we discover the existence of other minds as we discover the existence of bodies, by means of phenomena which are characteristic of minds, that is, which resemble those phenomena that follow the exertion of our own mental faculties, that is, by the employment of means to attain selfish ends; and where such appearances are not observed, no existence of a mind is inferred. When we see a man fall from the top of a house, and dash out his brains on the pavement, we never ascribe this motion to his mind. Although the fitness of many of the celestial motions for most important purposes makes us suppose design and contrivance somewhere, and therefore a *Supreme Mind*, we no more think of inferring a mind in the earth from the fitness of its motions for purposes most beneficial to its inhabitants, than of inferring a mind in a bit of bread from its fitness for nourishing our bodies. It is not from the mere motions of animals that their minds are inferred, but from the conduciveness of these motions to the well-being of the animal.

12
The term mind therefore, in the *ordinary language* of all men, is applied to what desires and wills at the same time that it perceives and understands. If we call that mind which *produces motion*, we must derive our notions of its qualities or attributes from observing their effects. We must therefore discover the general laws by which they act, that is, the general laws observed in those motions which we consider as their effects. Now these are the general laws of motion; and in none of these can we find the least coincidence with what we are accustomed to call the laws of mind. May it has been the total want of similarity which has given rise to the distinction which all men, in all ages and

Introduction.
100.

The mind is not that which produces motion, but that which desires and wills.

Introduction.

and countries, have made between mind and matter. This distinction is found in all languages; and it is an unpardonable liberty which men take with languages when they use a *term of distinction*, a *specific term*, to express things of a different species. What these authors have been pleased to call *mind*, the whole world besides have called by another name, *force*; which, though borrowed from our own exertions, is yet sufficiently distinctive, and never leads us to confound things that are different, except in the language of some modern philosophers, who apply it to the laws of the agency of mind; and, when speaking of the force of motives, &c. commit the same mistakes which the followers of Aristotle commit in the use of the term *mind*. *Force*, in the language of these philosophers, means what connects the operations of mind; as *mind*, in the language of Lord Monboddo, is that which connects the operations of body.

13
The principle of motion not distinct from matter and mind.

Those are not less to blame who consider this *Nature* of Aristotle, this principle of motion, as an existence or substance different both from matter and from the minds of intelligent creatures. Aristotle calls it in some places *ἀσπερ ψυχή*. He might with equal propriety, and equal consistency with his other doctrines, have called mind *ἀσπερ πνεύμα*, or an *ἀσπερ δυναμικόν*. Besides, we have no evidence for the separability of this *ἀσπερ ψυχή* from body as we have for the separability of such minds as our own, the genuine *ψυχαί*. Nay, his whole doctrines, when maturely considered, assume their absolute inseparability.

14
Elemental minds are an abuse of language.

This doctrine of elemental minds, therefore, as the immediate causes of the phenomena of the material world, is an abuse of language. It is a jargon; and it is a frivolous abuse, for it offers no explanation whatever. The phenomena are totally unlike the phenomena of ordinary minds, and therefore receive no explanation from them; and since our knowledge of these *quasi* minds must be derived entirely from the phenomena, it will be precisely the same, although we express it in common language. We shall not indeed raise the wonder of our hearers, as those do who fill the world with minds which they never suspected to exist; but we shall not bewilder their imaginations, confound their ideas, and mislead their judgments.

15
The dreadful consequences of materialism.

We flatter ourselves that our readers will not think these observations unseasonable or misplaced. Of all mistakes that the naturalist can fall into, there is none more fatal to his progress in knowledge than the confounding things which are essentially different; and of all the distinctions which can be made among the objects of our contemplation, there is none of equal philosophical importance with this between mind and matter: And when we consider the consequences which naturally follow from this confusion of ideas and particularly those which follow from sinking the mental faculties of man to a level with the operations of mechanics or chemistry, consequences which a little serious reflection will show to be destructive of all that is noble as desirable in human nature, and of all that is comfortable in this life, and which blunts every

hope of future excellence—we cannot be too anxious to have this capital distinction put in the plainest point of view, and expressed in the most familiar characters, “so that he who runneth may read.” When we see the frenzy which the reasoning pride of man has raised among some who call themselves philosophers, and hear the dictates of philosophy incessantly appealed to in defence of whatever our hearts shudder at as shocking and abominable; and when we see a man (A), of great reputation as a naturalist, and of professed humanity and political moderation, congratulating his countrymen on the rapid improvement and almost perfection of philosophy; and after giving a short sketch of the constitution of the visible universe, summing up all with a table of elective attractions, and that particular combination and mode of crystallization which constitutes *Gon* (*horresco referens!*)—is it not full time for us to stop short, and to ask our own hearts “whither are you wandering?”—But sound philosophy, reasoning from effects to their causes, will here listen to the words of our sacred oracles: “By their fruits ye shall know them. Do men gather grapes of thorns, or figs of thistles?” The absurd consequences of the sceptical philosophy of Berkeley and Hume have been thought, by men of undoubted discernment, sufficient reasons for rejecting it without examination. The no less absurd and the shocking consequences of the mechanical philosophy now in vogue should give us the same abhorrence and should make us abandon its dangerous road, and return to the delightful paths of nature, to survey the works of God, and feast our eyes with the displays of mind, which offer themselves on every hand in designs of the most extensive influence and the most beautiful contrivance. Following the guidance of heavenly wisdom we shall indeed find, that “all her ways are ways of pleasantness, and all her paths are peace.”

Introduction.

Such is the scene of our observation, the subject of philosophical study. Its extent is almost unbounded, reaching from an atom to God himself. It is absolutely necessary for the successful cultivation of this immense field of knowledge that it be committed to the care of different cultivators, and that its various portions be treated in different ways: and, accordingly, the various tastes of men have given this curiosity different directions; and the study, like all other tasks, has been promoted by this division of labour.

16
The extent of philosophical study.

Some philosophers have attended only to the appearances of fitness which are exhibited in every quarter of the universe; and by arranging these into different classes, and interpreting them as indications of thought and intention, have acquired the knowledge of many classes of sentient and intelligent beings, actuated by propensities, and directed by reason.

While the contemplation of these appearances indicates thought and design in any individual of one of these classes, and brings its propensities and purposes of action, and the ends gained by these actions, into view, the contemplation of these propensities, purposes, and ends, occasions an inference of a much more general

Introduc-
tion.

Introduc-
tion.

ral kind. All these intelligent beings give indications of knowledge and of power; but their knowledge bears, in general, no proportion to their power of producing changes in nature, and of attaining important ends; and their power is neither always, nor in the most important cases, the consequence of their knowledge. Where the effect of their actions is most eminently conducive to their important interests, the power of attaining these valuable ends is generally independent on any attention to the fitness of the means, and the exertion is frequently made without even thinking of the important end. The well-being of the individual is secured against any danger from its ignorance, indolence, or inattention, by an instinctive propensity, which leads it to the performance of the necessary action, which is thus made immediately and ultimately desirable, without any regard to its ultimate and important end. Thus, in our own nature, the support of animal life, and the improvement of the means of subsistence by a knowledge of the objects which surround us, are not intrusted to our apprehensions of the importance of these ends, but are committed to the surer guides of hunger and curiosity.

all the particular intention, and refer to them all; and thus it irresistibly leads them to trace the existence of a SUPREME MIND, directing the whole of this INTELLECTUAL SYSTEM, while the individual of which it consists appear the unconscious instrument in the hand of a great Artist, with which he executes his grand and beneficent purposes.

But the observation goes yet further. The bodies of the inanimate creation are not only connected with each other by a mutual dependence of properties, and the relation of causation, but they are also connected with the sentient beings by a subserviency to their purposes of enjoyment. The philosopher observes that this connection is admirably kept up by the constancy of natural operations and the expectations of intelligent beings. Had either of these circumstances been wanting, had either the operations of nature been without rule, or had sentient beings no perception or expectation of their uniformity; the subserviency would be totally at an end. This adjustment, this fitness, of which the effect is the enjoyment of the sentient inhabitants of the universe, appear to be the effect of an intention of which this enjoyment is the final cause. This constancy therefore in the operations of nature, both in the intellectual and material world, and the concomitant expectation of sentient beings, appear the effects of *laws* imposed on the different parts of the universe by the Supreme Mind, who has formed both these classes of beings so admirably suited to each other.

21
All nature
animate
and inani-
mate,
thinking
and un-
thinking,
are con-
nected.

18
There is a
connection
between
the indivi-
duals of a
class of ani-
mals dif-
ferent from
that of re-
semblance.

The same observers discover a connection between the individuals of a class, different from that which arises from the mere resemblance of their external appearance, or even of their propensities and pursuits; the very circumstances which produced the classification. They observe, that these propensities are such, that while each individual seeks only its own enjoyment, these enjoyments are in general such as contribute to the support of the species and the enjoyment of other individuals. Thus, in the classes of animals, and in human nature, the continuance of the race, and the enjoyment of the whole, are not entrusted to the apprehension we entertain of the importance of these ends, but are produced by the operation of sexual love and the love of society.

To such observers the world appears a WORK OF ART, a system of means employed for gaining certain proposed ends, and it carries the thoughts forward to an ARTIST; and we infer a degree of skill, power, and good intention in this Artist, proportioned to the ingenuity, extent, and happy effect which *we are able to discern* in his works. Such a contemplation of nature, therefore, terminates in NATURAL THEOLOGY, or the discovery of the existence and attributes of God.

22
The origin
of natural
theology.

19
There is
also a link
of connec-
tion be-
tween sen-
tient be-
ings of dif-
ferent clas-
ses.

The same observers find that even the different classes of sentient beings are connected together; and while the whole of each class aim only at their own enjoyment, they contribute, in some way or other, to the well being of the other classes. Even man, the selfish lord of this sublunary world, is not the unconnected inhabitant of it. He cannot, in every instance, reap all the fruits of his situation, without contributing to the enjoyment of thousands of the brute creation. Nay, it may be proved to the satisfaction of every intelligent man, that while one race of animals, in consequence of its peculiar propensities, subsists by the destruction of another, the sum total of animal life and enjoyment is prodigiously increased. See a very judicious dissertation on this curious and puzzling subject, entitled *A Philosophical Survey of the Animal Creation*; where it appears that the increase of animal life and enjoyment which is produced by this means, beyond what could possibly obtain without it, is beyond all conception. See likewise the last edition of *King's Origin of Evil*, by Dr Law late bishop of Carlisle.

Our notions of this *Supreme Mind* are formed from the indications of design which we observe, and which we interpret in the same way as in the actions of men. These notions, therefore, will differ from our notions of other minds only in the *degrees* which we are able to observe, and which we assign to these faculties; for the phenomenon or the effect is not only the mark, but also the measure of its supposed cause. These degrees must be ascertained by our own capacity of appreciating the extent, the multiplicity, and the variety of the contrivance. Accordingly, the attributes of the Supreme Mind, in the theological creed of a rude Indian, are much more limited than in that of a European philosopher. In proportion as our understandings are enlarged, and as our acquaintance with the operations of nature around us is extended, we shall perceive higher degrees of power, of skill, and of kind intention: and since we find that the scene of observation is unbounded, we can not asfix any boundaries to these attributes in our own imagination, and we are ready to suppose that they are infinite or unbounded in *their own nature*. When our attentive survey of *this universe*, and a careful comparison of all its parts, as far as we can understand or appreciate them, have made us conclude that it is *one* design, the work of *one*

mulation
of happi-
ness.

That the whole assemblage seems connected, and jointly employed in increasing the sum total of possible happiness. This fitness of the various propensities of sentient and intelligent beings, this subserviency to a general purpose, strikes these observers as a mark of intention, evidently distinct from, and independent of,

Introduction. *Artist*; we are under the necessity of inferring, that, with respect to *this universe*, his power, wisdom, and benevolence, are indeed infinite

24 The system of nature is governed by general laws. When men have been led to draw this conclusion from the appearances of fitness which are observed everywhere around them, they consider that constancy which they observe in natural operations, whether in the material or the intellectual system, and that expectation of, and confidence in, this constancy, which renders the universe a source of enjoyment to its sentient inhabitants, as the consequences of laws imposed by the Almighty Artist on his works, in the same manner as they would consider the constancy in the conduct of any people as the consequences of laws promulgated and enforced by the supreme magistrate.

25 The nature and progress of the study of mind. There can be no doubt of this view of nature being extremely captivating, and likely to engage the curiosity of speculative men; and it is not surprising that the phenomena of mind have been keenly studied in all ages. This part of the study of nature, like all others, was first cultivated in subserviency to the wants of social life; and the general laws of moral sentiment were the first phenomena which were considered with attention. This gradually ripened into a regular system of moral duty, accompanied by its congenial study, the investigation or determination of the *summum bonum*, or the constituents of human felicity; and these two branches of intellectual science were always kept in a state of association by the philosophers of antiquity.

26 The rise of moral sentiments and of moral duty. Jurisprudence, the science of government, legislation, and police, were also first cultivated as arts, or at least in immediate subserviency to the demands of cultivated society; and all these so nearly related parts of the study of human nature, had made a very considerable progress, in the form of maxims or precepts, for directing the conduct, before speculative men, out of mere curiosity, treated them as subjects of philosophical study. Our moral sentiments, always involving a feeling of obligation, are expressed in a language considerably different from the usual language of pure philosophy, speaking of things which *ought to be*, rather than of things which *are*; and this distinction of language was increased by the very aim of the writers, which was generally to influence the conduct as well as the opinions of their scholars. It was reserved for modern times to bring this study into the pure form of philosophy, by a careful attention to the phenomena of moral sentiment, and classing these according to their generality, and ascertaining their respective ranks by an appeal to experiment, that is, to the general conduct of mankind: and thus it happens that in the modern treatises on ethics, jurisprudence, &c. there is less frequent reference made to the *officia* or duties, or to the constituents of the *summum bonum*, than among the ancients, and a more accurate description of the human mind, and discrimination of its various moral feelings.

27 The origin of logic and other intellectual sciences. It was hardly possible to proceed far in these disquisitions without attending to the powers of the understanding. Differences of opinion were supported by reasonings, or a tempts to reasoning. Both sides could not be in the right, and there must be some court of appeals. Rules of argumentation behaved to be acquiesced in by both parties; and it could hardly

escape the notice of some curious minds, that there were rules of truth and falsehood as well as of right and wrong. Thus the human *understanding* became an object of study, first in subserviency to the demands of the moralists, but afterwards for its own sake; and it gradually grew up into the science of logic. Still further refinement produced the science of metaphysics, or the philosophy of universals. But all these were *in fact* posterior to the doctrines of morals; and disquisitions on beauty, the principles of taste, the precepts of rhetoric and criticism, were the last additions to the study of the phenomena of mind. And now, since the world seems to have acquired in the mode of investigation of general laws by experiment and observation, and to agree that this is all the knowledge that we can acquire of any subject whatever, it is to be expected that this branch of philosophical discussion will attain the same degree of improvement (estimated by the coincidence of the doctrines with fact and experience) that has been attained by some others.

28 The partial practice of natural philosophy preceded its study as a science. The occupations, however, of ordinary life have often directed our efforts towards material objects, and engaged our attention on their properties and relations; and as all sciences have arisen from arts, and were originally implied in the maxims and precepts of those arts, till separated from them by the curious speculatist, the knowledge of the material system of nature was possessed in detached scraps by the practitioners in the various arts of life long before the *natural philosopher* thought of collecting them into a body of scientific doctrines. But there have not been wanting in all ages men of curiosity who have been struck by the uniformity of the operations of nature in the material world, and were eager to discover their causes.

Accordingly, while the moralists and metaphysicians turned their whole attention to the phenomena of mind and have produced the sciences of pneumatology, logic, ethics, jurisprudence, and natural theology, these observers of nature have found sufficient employment in considering the phenomena of the material world.

29 The nature of the material system with the definition of that and other terms. The bodies of which it consists are evidently connected by means of those properties by which we observe that they produce changes in each other's situation. This assemblage of objects may therefore be justly called a system. We may call it the MATERIAL SYSTEM. It is frequently termed NATURE; and the terms NATURAL APPEARANCES, NATURAL CAUSES, NATURAL LAWS, have been generally restricted to those which take place in the material system. This restriction, however, is improper, because there is no difference in the manner in which we form our notions of those laws, and reason from them, both with respect to mind and body. Or if there is to be any restriction, and if any part of the study of the universe is to be excluded in the application of these terms, it is that part only which considers moral obligation, and rather treats of what *ought to be* than of what *is*. As has been already observed, there is a considerable difference in the language which must be employed; but still there is none in the principles of investigation. We have no proof for the extent of any moral law but

of agricul-
ture, phy-
sic, surgery,
and che-
mistry.

procuring them, depending on their manner of life or existence. It required a studied attention to these circumstances to give rise to agriculture, which therefore generally made its appearance after men had been in the practice of keeping flocks; by which means they were more at their ease, and had some leisure to attend to the objects around them, and in particular to those circumstances of soil and weather which affected the growth of their pasture.

When agriculture and a rude medicine were thus established, they were the first *arts* which had their foundation in a *system of laws*, by which the operations of nature were observed to be regulated; and with these arts we may begin the *general study of nature*, which were thus divided into two different branches.

The rude physician would be at first a collector of *specifics*; but by degrees he would observe resemblances among the *operations* of his drugs, and would class them according to these resemblances. He would thus come to attend less to the drug than to its mode of operation; and would naturally speculate concerning the connection between the operation and the economy of animal life. His art now becomes a scientific system, connected by principle and theory, all proceeding on the observation of changes produced by one kind of matter on another, but all out of sight. The frequent recourse to the vegetable kingdom for medicines would cause him to attend much more minutely to the few plants which he has occasion to study than the husbandman can do to the multitude he is obliged to rear. The physician must learn to think, the husbandman to work. An analogy between the economy of animal and vegetable life could hardly fail to engage the attention of the physician, and would make him a botanist, both as a classifier of plants and as a philosopher.

He would naturally expect to unite the services of his drugs by combining them in his recipes, and would be surprised at his disappointments. Curious and unexpected changes would frequently occur in his manipulations: the sensible qualities, and even the external appearances of his simples, would be often changed, and even inverted by their mixture; and their medicinal properties would frequently vanish from the compound, and new ones be induced. These are curious, and to him interesting facts; and he would naturally be inquisitive after the principles which regulate these changes. His skill in this would by degrees extend beyond the immediate use for the knowledge; and the more curious speculatist would lay the foundations of a most extensive and important science, comprehending all the phenomena of heat and mixture.

Along with this, and springing from the same source, another science must arise, contemplating the appearances of animal and vegetable life, and founded on a careful observation and accurate description of the wonderful machine. The most incurious of men have in all ages been affected by the displays of wisdom and contrivance in the bodies of animals, and immediately engaged in investigation into the uses and functions of their various parts and organs. The phenomena have been gradually discriminated and arranged under the various heads of nutrition, concoction, secretion, absorption, assimilation, rejection, growth, life, decay, disease, and death; and, in conformity to the doctrines

which have with greater or less evidence been established on these subjects, the action of medicines, and the whole practice of physic and surgery, has been established in the form of a liberal or scientific art.

The husbandman in the mean time must labour the ground which lies before him. He, too, is greatly interested in the knowledge of the vegetable economy, and forms some systems on the subject by which he regulates his labours: but he sees, that whatever is the nature of vegetable life, he must work hard, and he searches about for every thing which can tend to diminish his labour. The properties of the lever, the wedge, and the inclined plane, soon become familiar to him; and without being able to tell on what their efficacy depends, he uses them with a certain sagacity and effect. The strength of timber, the pressure and force of water, are daily seen and employed by him and other artificers who labour for their mutual accommodation; and some rude principles on these subjects are committed to memory. Many tools and simple machines are by this time familiar; and thus the *general* properties of matter, and the general laws of the actions of bodies on each other, become gradually matter of observation and reflection; and the practical mechanic will be frequently improving his tools and machines. The general aim is to produce a greater quantity of work by the same exertion. The attempts to improvement will be awkward, and frequently unsuccessful. When a man finds, that by increasing the length of his lever he increases his power of overcoming a resistance, a small degree of curiosity is sufficient to make him inquire in what proportion his advantage increases. When he finds that a double length gives him a double energy, he will be surprised and mortified to find, that at the end of the day he has not performed twice the quantity of work: but, after much experience, he will learn that every increase of energy, by means of a machine, is nearly compensated by an increase of time in the performance of his task; and thus one of the great and leading principles of practical mechanics was inculcated in a manner not to be forgotten, and the practical mechanic was brought to speculate about motion and force, and by gradual and easy steps the general laws of simple motions were established.

It is evident that these speculations cannot be carried on, nor any considerable knowledge acquired, without some acquaintance with the art of measurement: and the very questions which the mechanic wishes to solve, presuppose some advances in this art, which in process of time refined itself into mathematics, the most perfect of all the sciences. All the phenomena of sensible motion afford employment to the mathematician. It is performed in a double or triple time, through a double or triple space, by a double or triple body, by the exertion of a double or triple force, produces a double or triple effect, is more to the right or to the left, upwards or downwards, &c. In short, every affection of motion is an object of mathematical discussion. Such a science must have appeared ere now in the form of an art, in consequence of the mutual transactions of men. They among an uncultivated people are chiefly in the way of barter. If I want corn from a peasant, and have nothing to give for it but the cloth which I have made, we must fall on some way

way of adjusting our terms in respect of the quantity. We should soon discover that the length, and breadth, and depth, of the box or bag, were equally important; and it was not difficult to see, that if any of them were doubled or tripled, the quantity of grain would be so too; if two of them were doubled, the grain would be quadrupled; and if all the three were doubled the quantity of grain would be increased eight times: the same thing would be observed with respect to my cloth. By such transactions as these, a few of the properties of plane and solid numbers and figures would become known, and the operations of multiplication and division, where arithmetic is combined with geometry, and daily observation shows us, that the more abstruse properties of number and figure, which to the generality of mankind are so insignificant, lay hold on the fancy of some individuals with such force, as to abstract them from every other intellectual entertainment, and are studied with a keenness and perseverance almost unequalled in any other walk of science. To most men the performance of a machine is a more attractive object than the properties of a figure, and the property of a figure more entertaining than that of a number; but the fact seems to have been otherwise. Before Pythagoras had invented the theorem that bears his name (see PHILOSOPHY, n° 15. and note H.), and which is among the first elements of geometry, he had reformed the Grecian music by the addition of a note to their scale, and this addition proceeds on a very refined speculation on the properties of numbers; so that among the Greeks arithmetic must have made considerable progress, while geometry was yet in its cradle: and we know to what astonishing length they prosecuted the science of pure geometry, while their knowledge of mechanical principles was almost nothing. Also the Arabs hardly made any addition to the geometry of the Greeks, if they did not rather almost completely forget it; whilst they improved their arithmetic into algebra, the most refined and abstracted branch of human knowledge. There is such a distance, in point of simplicity, between pure mathematics and the most elementary mechanics, that the former continued to make rapid steps to improvement in more modern times, while the latter languished in its infancy, and hardly deserved the name of science till very lately, when the great demand for it, by the increase and improvement in manufactures, both interested many in the study, and facilitated its progress, by the multitude of machines which were contriving on all hands by the manufacturers and artificers: and even at present it must be acknowledged, that it is to them that we are indebted for almost every new invention in mechanics, and that the speculatist seldom has done more than improve the invention, by exhibiting its principles, and thus enabling the artist to correct its imperfections; and now science and art go hand in hand, mutually giving and receiving assistance. The demands of the navigator for mathematical and astronomical knowledge have dignified these sciences; and they are no longer the means of elegant amusement alone but merit the munificence of princes, who have erected observatories, and furnished voyages of discovery, where the mathematical sciences are at the same time cherished and applied to the most important purposes.

This short sketch of what may be called *the natural*

history of physical science will not, we hope, be thought improper or unprofitable. It tends to confirm an assertion often alluded to, that the prosecution of the study of nature will be more successful, if we imitate her mode of proceeding, and divide the labour. It will be still further confirmed by attending to the scientific difference of the phenomena, which marks out a different mode of proceeding, and a difference in the knowledge which we shall ultimately acquire, after our most successful researches.

In both classes of phenomena already distinguished (n° 6.) we must grant, that the principle which connects the pairs of concomitant events, rendering the one the inseparable companion of the other, is totally unknown to us, because it is not the immediate object of our perception.

But in the phenomena of the first class, we see the *immediate* exertion of this principle, whatever it may be; we can observe the exertion with accuracy; we can determine its kind and degree, which are the signs and measures of the kind and degree of the unperceived cause. This exertion, being always some modification of motion, allows us to call in the aid of mathematical knowledge, and thus to ascertain with the precision peculiar to that science the energy of the cause, judging of the tendency and quantity by the tendency and the quantity of the observed effect.

But in the second class of phenomena the case is very different. In the operations of chemistry, for instance, the *immediate* exertion of the cause is not perceived: all that we observe is the assemblage of particles which obtains before mixture, and that which takes place when it is completed, and which we consider as its result. The procedure of nature in producing the change is unseen and unknown. The steps are hid from our observation. We are not only ignorant of the cause which determines one particle of our food to become a part of our body while others are rejected, but we do not see the operation. We are not only ignorant of the cause which determines a particle of vitriolic acid to quit the fossil alkali with which it is united in Glauber salt, and to attach itself to a particle of magnesia already united with the muriatic acid, which also quits it to unite with the alkali, but we do not see the operation. The particles and their motions are not the objects of our senses; and all that we see is the Epsom salt and common salt separated from the water in which we had formerly dissolved the sal mirabile and the muriated magnesia. The motions, which are the *immediate* effects of the changing causes, and therefore their *only indications, characteristics, and measures*, fitted to show their nature, are hid from our view.

Our knowledge therefore of these phenomena must be less perfect than that of the phenomena of the former class; and we must here content ourselves with the discovery of more remote relations and remote causes, and with our ignorance of the very powers of nature by which these changes are brought about, and which are cognoscible only by their immediate effects, *viz.* the motions which they produce unseen. The knowledge which we do really acquire is somewhat similar to what the mechanical philosopher has acquired when he has discovered, by many experiments and investigations, that magnets attract each other by their dis-

40

tion.

similar poles, and repel each other by their similar poles, and do not act at all on any bodies but loadstones and iron. Here we have undiscovered all that is most curious in the phenomenon, *viz.* how these attractions and repulsions are produced: and even here the magnetical philosopher has the advantage of seeing the agents and the operation.

44
Though
some philo-
sophers
have at-
tempted
to explain
them by
the doc-
trine of
motion;

But philosophers attending to this circumstance, that, even in these cases, the changes are produced by motions, or consist in motions, however unperceived these may be, have concluded, that the laws according to which nature operates in producing these changes are similar to the laws which regulate her operations in the sensible actions of bodies, or are included in them; and that the motions, though unseen, and the moving forces are perfectly similar. They have therefore employed similar modes of investigation, applying the laws of impulse, and calling in the aid of mathematical knowledge.

Of this we have many examples in the writings of Dr Freind, Keil, Bernoulli, Helsham, Berhaave, Hartley, and others, who have delivered theories of fermentation, solution, precipitation, crystallization, nutrition, secretion, muscular action, nay even of sensation and intelligence, founded, as they think, on the laws of motion, and illustrated and supported by mathematical reasoning. Lord Bacon himself, that careful and sagacious distinguisher of intellectual operations, has gone into the same track in his explanation of the phenomena of fire and combustion: and Sir Isaac Newton has made several attempts of the same kind, although with peculiarities which always characterize his discussions, and make them very different from those of an inferior class.

45
But their
attempts
have been
unsuccess-
ful.

But the success of these philosophers has hitherto been very discouraging: indeed they had no title to expect any; for their whole trains of reasoning have proceeded on analogies which were not observed, but assumed or *supposed* without any authority. There is not that similarity in the phenomenon, or in the visible effect, which is absolutely necessary for a successful reasoning by analogy. We do not observe any local motion, any change of place, which alone enables us to reason mathematically on the subject. And to make the case desperate, this ill founded analogy has been mixed with hypotheses completely gratuitous. Certain forms have been assigned to the particles, and certain modes of action have been laid down for them, for whose reality we have not the least argument or indication: and to complete the matter, these fancied forms and laws of action have been such as are either self contradictory and inconsistent, or they have been such as, if allowed to act in a way analogous to what we observe in the sensible motions of bodies, would produce effects totally different from those which are observed. These atomical theories, as they are called, transgress every rule of philosophical discussion, and even the best of them are little better than trifling amusements. By far the greatest part of them only serve to raise a smile of pity and contempt in every person at all acquainted with mechanical philosophy. Whenever we see an author attempting to explain these hidden operations of nature by invisible fluids, by atoms, by collisions, and vibrations, and particularly if we see him introducing ma-

thematical reasonings into such explanations—the best thing we can do is to shut the book, and take to some other subject. That we may not be thought to speak presumptuously on this occasion, we only beg leave to remind our readers, that the united knowledge of the most eminent mathematicians of Europe has not yet been able to give any thing more than an approximation to the solution of the problem of three bodies; that is, to determine with accuracy the motions of three particles of matter acting on each other in the simplest of all possible manners, *viz.* by forces varying as the squares of the distances inversely: and the vibrations of elastic bodies, of any but the very simplest possible forms, are to this day beyond the reach of investigation. What then should be our expectations in cases where millions of particles are acting at once, of forms unobserved, and with forces unknown, and where the object is not a determination of an average result of many, where the precise state of an individual particle need not be known, but where it is this very precise state of each single particle that we want to know? What can it be but uncertainty and mistake?

Notwithstanding these discouraging circumstances, we must observe that this kind of inquiry has greatly improved of late years, along with the improvement and extension of mathematical philosophy, and since philosophers have given over their incessant attempts to explain every thing by impulse; and we need not despair of making still farther advances, if we will content ourselves with going no farther than Newton has done in his explanation of the planetary motions. He has immortalized his own name, and has added immensely to our stock of useful knowledge: yet he has stopped short at the discovery of the fact of universal gravitation; and all who have endeavoured to explain or account for this fact have only exposed themselves to pity. We may perhaps one day be able to demonstrate from the phenomena that the particles of matter have certain mutual tendencies to or from each other, exerted according to fixed or invariable rules; and from these tendencies we may be able to explain many other phenomena, and predict the consequences, with as much certainty and evidence as an astronomer calculates a future eclipse. This would be a great acquisition, and perhaps more is impossible: and the road to this has been hinted by Sir Isaac Newton, who has expressed his suspicion, that as the great movements of the solar system are regulated by universal gravitation, so the mutual actions of the particles of matter are produced and regulated by tendencies of a similar kind, *equally* but not *more* inexplicable, and of which the laws of action are to be discovered by as careful an attention to the phenomena, and by the same patient thinking, which he has employed on the planetary motions. And a beautiful introduction to this new and almost unbounded field of enquiry has been given us by the celebrated Abbé Bossovich, in his Theory of Natural Philosophy, where he has shown how such mutual tendencies, similar in every ultimate particle of matter, and modified by conditions that are highly probable, nay almost demonstrable, will not only produce the sensible forms of solidity, hardness, elasticity, ductility, fluidity, and vapour, under an inconceivable variety

tion.

variety of subordinate appearances, and the observed laws of sensible motion, but will go far to explain the phenomena of fusion, congelation, solution, crystallization, &c. &c. &c. both in chemistry and physiology. We earnestly recommend this work to the perusal of all who wish to obtain a distinct notion of the internal constitution of natural bodies, and of the way in which the uniting forces produce their ultimate and sensible effects. Any person, possessed of a moderate share of mathematical knowledge, will be convinced that the process of nature is not very different from what he describes; and that much of what we observe must happen as he says, even although the ultimate atoms of matter are not extended mathematical points, accompanied with attracting and repelling forces.

47
Our igno-
rance still
great, and
the proba-
ble increase
of know-
ledge a-
mong po-
sibility.

But we have many steps to make before we begin this study: Nature opens to us an immense volume; and we doubt not that our posterity will long find employment in the perusal, even though advancing with the eagerness and success of the last century. We have not yet arrived at the threshold in many parts of this research: In many parts of chemistry, for instance, we are as yet uncertain with respect to the phenomena themselves, which are to be the subjects of this discussion. The composition of bodies must be fully understood before we begin to speak of the forces which unite their particles, or speculate about their modes of action. As long as water was considered as an element, we were ignorant of the forces inherent in its particles; we are perhaps still ignorant of this: but we now know that they are extremely different from what we formerly supposed them to be. It is but in a very few, if in any, cases of chemical combination, that we even know what are the ingredients: till we know this, it is too soon to speculate about their mode of union. Our ignorance in the real events in the animal and vegetable economy is still greater. Our first task therefore is to proceed, as we are now doing, in the accurate examination and classification of the phenomena themselves; and, without attempting to bring them within the pale of mathematical philosophy, by attempting what are called mechanical explanations, let us give up the consideration of these hidden operations, and augment to the utmost our list of secondary laws of visible but remote connections. All the mechanical speculations of the honourable Robert Boyle about the sensible qualities of things are now forgotten; but his chemical experiments preserve all their value, and are frequently referred to. The same may be said of the sagacious Dr Hales, whose fanciful notions of internal conflicts, and collisions, and vibrations, derogate nothing from the value of the curious facts which he has established both in the animal and vegetable economy.

48
The partic-
ular divi-
sions of
physical
science in
Britain.

This distinction in the nature of the phenomena, and this difference in the nature of the knowledge which is to be acquired, and the means which are to be employed for the successful prosecution of these two branches of general physics, has occasioned a still further restriction (at least in Britain) of the term NATURAL PHILOSOPHY. It is particularly applied to the study of the phenomena of the first class, while those of the second have produced the sciences of CHEMISTRY and PHYSIOLOGY.

Intro-
duction.

Natural philosophy and chemistry have generally been made particular institutions in our seminaries of learning, but physiology has more commonly been taught in conjunction with anatomy, medicine, and botany.

The phenomena of the first class have been usually called MECHANICAL, in order to distinguish them from those observed in the operations of chemistry, and in the animal and vegetable economy; and the explanations which have been attempted of some of the last, by applying the laws observed in the phenomena of the first class, have been called *mechanical explanations*.

As this first class is evidently but a part of general physics, there is some impropriety in giving the name *natural philosophy* to a course of doctrines which is confined to these alone. Indeed at the first institution of universities, the lectures given in the *Schola Physica* were much more extensive, comprehending almost all the phenomena of the material world; but as all arts and sciences have improved most where the labour has been most divided, it was found more conducive to the advancement of knowledge that separate institutions should be founded for the studies of natural history, chemistry, physiology, &c.; and thus the phenomena, purely mechanical, and a few others in magnetism, electricity, and optics which either were susceptible of mathematical treatment, or had little connection with the studies of chemistry and physiology, were left to the care of the professor of natural philosophy.

As the terms *chemistry* and *physiology* have been applied to two very important branches of general physics, we think that a more specific or characteristic name might be appropriated to the other, and that it might very properly be termed MECHANICAL PHILOSOPHY.

It only remains to make a few observations on the distinctive means of prosecuting these studies with success, and to point out some of the advantages which may reasonably be expected from a careful prosecution of them: and as the second branch has been fully treated under the several articles of CHEMISTRY, PHYSIOLOGY, &c. we shall confine ourselves to what is usually called NATURAL PHILOSOPHY.

MECHANICAL PHILOSOPHY may, in conformity with the foregoing observations, be defined, "the study of the sensible motions of the bodies of the universe, and of their actions producing sensible motions, with the view to discover their causes, to explain subordinate phenomena, and to improve art."

49
Mechanical
philosophy
defined,
and its
principles
explained.

The principle upon which all philosophical discussion proceeds is, that *every change which we observe in the condition of things is considered by us as an effect, indicating the agency, characterizing the kind, and measuring the degree, of its cause.*

In the language of mechanical philosophy, the cause of any change of motion is called a moving or changing FORCE.

The disquisitions of natural philosophy must therefore begin with the consideration of motion, carefully noticing every affection or quality of it, so as to establish marks and measures of every change of which it is susceptible; for these are the only marks and mea-

asures

Mechanical Philosophy
50
The laws of motion and their application.

of the changing forces. This being done, it only remains to apply them to the motions which we observe in the universe.

From the general principle of philosophical discussion already mentioned, there flow directly two axioms.

1. Every body performs in a plane of rest or of uniform rectilinear motion, unless affected by some moving force.

2. Every body of motion is in the direction and in the degree of the force applied.

They are usually called the LAWS OF MOTION. They are more properly laws of human judgment, with respect to motion. Perhaps they are necessary truths, unless it be alleged that the general principle, of which they are necessary consequences, is itself a contingent though universal truth.

By these two axioms, applied *in abstracto* to every variety of motion, we establish a system of general doctrines concerning motions, according as they are simple or compounded, accelerated, retarded, rectilinear, curvilinear, in simple bodies, or in systems of connected bodies; and we obtain corresponding characteristics and measures of accelerating or retarding forces, centripetal or centrifugal, simple or compound.

We have an illustrious example of this abstract system of motion and moving forces in the first book of Sir Isaac Newton's Mathematical Principles of Natural Philosophy. Euler's *Mechanica sive Scientia Motus*, Herman's *Phoronomia sive de Viribus Corporum*, and D'Alembert's *Traité de Dynamique*, are also excellent works of the same kind. In this abstract system no regard is paid to the casual differences of moving forces, or the sources from which they arise. It is enough to characterize a double accelerating force, for instance, that it produces a double acceleration. It may be a weight, a stream of water, the pressure of a man; and the force, of which it is said to be double, may be the attraction of a magnet, a current of air, or the action of a spring.

Having established these general doctrines, the philosopher now applies them to the *general* phenomena of the universe, in order to discover the nature of the forces which really exist, and the laws by which their operations are regulated, and to explain interesting but subordinate phenomena. This is the chief business of the mechanical philosopher; and it may with some propriety be called *the mechanical history of nature*.

Some method must be followed in this history of mechanical nature. The phenomena must be classed by means of their resemblances, which infer a resemblance in their causes, and these classes must be arranged according to some principle. We have seen no method which appears to us less exceptionable than the following.

51
Of the arrangement of the mechanical phenomena of the universe.

The principle of arrangement is the generality of the phenomena; and the propriety of adopting this principle, arises from the probability which it gives us of more readily discovering the most general actuating forces, whose agency is implicated in all other phenomena of less extent; and therefore should be previously distinguished, that we may detect the discriminating circumstances, which serve to characterize the subordinate

52
The generality of the phenomena is the principle of arrangement.

phenomena, and are thus the marks of the distinguishing and inferior natural powers.

The most general of all phenomena is the curvilinear motion of bodies in free space; it is observed through the whole extent of the solar system.

The mechanical history of nature begins therefore with astronomy. Here, from the general phenomena of the planetary motions, is evinced the fact of the mutual deflection of every body towards every other body, and this in the inverse proportion of the squares of the distance, and the direct proportion of the quantity of matter. This is the fact of UNIVERSAL GRAVITATION, indicating the agency, and measuring the intensity, of the universal force of mutual gravity.

Having established this as an universal fact, the natural philosopher proceeds to point out all the particular facts which are comprehended under it, and whose peculiarities characterize the different movements of the solar system. That is, in the language of philosophy, he gives a theory or explanation of the subordinate phenomena; the elliptical motions of the planets and comets, their mutual disturbances; the lunar irregularities; the oblate figure of the planets; the nutation of the earth's axis: the precession of the equinoxes; and the phenomena of the tides and trade winds; and he concludes with the theory of the parabolic motion of bodies projected on the surface of this globe, and the motion of pendulums.

As he goes along, he takes notice of the applications which may be made to the arts of life of the various doctrines which are successively established; such as chronology, astronomical calculation, dialling, navigation, gunnery, and the measuring of time.

If a square parcel of sand be lying on the table, and the finger be applied to any part of it to push it along the table, that part is removed where you will, but the rest remains in its place; but if it is a piece of sandstone of the same materials and shape, and the finger is applied as before, the whole is moved; the other parts accompany the part impelled by the finger in all its motions.

From the moon's accompanying the earth in all its motions round the sun, we infer a moving force which connects the moon and earth. In like manner, we must conclude that a moving force connects the particles of the stone; for we give the name *force* to every thing which produces motion: We call it the force of COHESION; a term which, like gravitation, expresses merely a fact.

This seems to be the next phenomenon of the universe in point of extent.

Having from the general phenomenon, established the evidence of this force, the philosopher proceeds to ascertain the laws by which its exertions are regulated; which is the ascertaining its distinctive nature and properties. This he does in the same way that he ascertained the nature of planetary gravitation, *viz.* by observing more particularly the various phenomena.

Here is opened a most extensive and varied field of observation, in which it must be acknowledged that very little regular and marked progress has been made. The variety of the phenomena, and the consequent variety in the nature of the connecting forces, appear as yet incalculably great, and there seems little probability

55
The nature of gravitation.

56
And of cohesion.

57
Mode of investigating the laws of cohesion.

Mechanical Philosophy bability of our being able to detect in them all any lameness, combined with the other distinguishing circumstances, as we have done in the case of gravity. Yet we should not despair. Boscovich has shown, in the most unexceptionable manner, that although we shall suppose that every atom of matter is endued with a perfectly similar force, acting in a certain determined ratio of the small and imperceptible distances at which the particles of matter are arranged with respect to each other, the external or sensible appearances may, and must, have all that variety which we observe. He also shews very distinctly how, from the operation of this force, must arise some of the most general and important phenomena which characterize the different forms of tangible bodies.

We observe the chief varieties of the action of this CORPUSCULAR force on the bodies which we denominate *hard, soft, solid, fluid, vaporous, brittle, ductile, elastic*. We see instances where the parts of bodies avoid each other, and require external force to keep them together, or at certain small distances from each other. This is familiar in air, vapours, and all compressible and elastic bodies.

This is evidently a most curious and interesting subject of investigation. On the nature and action of these corpuscular forces depends the strength or firmness of solids, their elasticity, their power of communicating motion, the pressure, and motion, and impulse of fluids; nay, on the same actions depend all the chemical and physiological phenomena of expansion, fusion, congelation, vaporisation, condensation, solution, precipitation, absorption, secretion, fermentation, and animal and vegetable concoction and assimilation.

Out of this immense store of phenomena, this inexhaustible fund of employment for our powers of investigation, the natural philosopher selects those which lead directly to the production or modification of sensible motion.

He will therefore consider,

1. The communication of motion among detached and free bodies, establishing the laws of impulse or collision. This has always been considered as the elementary doctrine of mechanical philosophy, and as the most familiar fact observed in the material world; and in all ages philosophers have been anxious to reduce all actions of bodies on each other to impulse, and have never thought a phenomenon completely explained or accounted for till it has been shewn to be a case of impulse. This it is which has given rise to the hypotheses of vortices, ethers, magnetic and electric fluids, animal spirits, and a multitude of fancied intermediums between the sensible masses of matter, which are said in common language to act on each other. A heavy body is supposed to fall, because it is impelled by a stream of an invisible fluid moving according to certain conditions suited to the case. The filings of iron are supposed to be arranged round a magnet, by means of a stream of magnetic fluid issuing from one pole, circulating perpetually round the magnet, and entering at the other pole, in the same manner as we observe the stote grafs arranged by the current of a brook.

But the philosopher who has begun the mechanical study of nature by the abstract doctrines of dynamics, and made its first application to the celestial phenomena, and who has attended carefully to the many ana-

logies between the phenomena of gravitation and cohesion, will be at least ready to entertain very different notions of this matter. He will be so far from thinking that the production of motion by impulse is the most familiar fact in nature, that he will acknowledge it to be comparatively very rare; nay, there are some appearances in the facts which are usually considered as instances of impulsion, which will lead him to doubt, and almost to deny, that there has ever been observed an instance of one body putting another in motion by coming into absolute contact with it, and striking it; and he will be disposed to think that the production of motion in this case is precisely similar to what we observe when we gently push one floating magnet towards another, with their similar poles fronting each other. There will be the same production of motion in the one and diminution of it in the other, and the same uniform motion of the common centre of gravity: and, in this case of the magnet, he sees completely the necessity of a law of motion, which is not an axiom, but is observed through the whole of nature, and which receives no explanation from any hypothesis of an intervening fluid, but is even totally inconsistent with them. We mean, "that every action of one body on another is accompanied by an equal and opposite action of that other on the first." This is usually called the *equality of action and reaction*: it is not intuitive, but it is universal; and it is a necessary consequence of the perfect similarity of the corpuscular forces of the same kinds of matter. This general fact, unaccountable on the hypothesis of impelling fluids, is considered in the planetary motions as the unequivocal indication of the lameness of that gravity which regulates them all. The rules of good reasoning should make us draw the same conclusion here, that the particles of tangible matter are connected by equal and mutual forces, which are the *immediate causes* of all their sensible actions, and that these forces, like gravitation, vary with every change of distance and situation.

The laws of collision and impulsion bring now established, either as original facts or as consequences of the agency of equal and mutual forces which connect the particles of matter, the philosopher considers,

2. The production of motion by the intervention of solid bodies, where, by reason of the cohesion of matter, some of the motions are necessarily confined to certain determinate paths or directions. This is the case in all motions round fixed points or axes, or along planes or curves which are oblique to the action of the forces.

This part of the study contains the theory of machines, pointing out the principles on which their energy depends, and consequently furnishing maxims for their construction and improvement. But these observations do not complete the discussion of the mechanism of solid bodies: they are not only solid and inert, but they are also heavy; therefore the action of gravity must be combined with the consequences of solidity. This will lead to discussions about the centre of gravity, the theory and construction of arches and roofs, the principles of stability and equilibrium, the attitudes of animals, and many particulars of this kind.

3. The philosopher will now turn his attention to another form, in which tangible matter exhibits many interesting phenomena, *viz.* FLUIDITY. The first thing

Mechanical Philosophy

60
Motion seems to be produced from the equality of action and reaction.

Of motion as it respects the theory of machines, &c.

62
MACHINES.

63
The nature and description of fluidity.

58
The production of motion by impulse has been thought the most familiar fact in nature.

59
But this opinion is very questionable.

Mechanical Philosophy

to be attended to here is, *What is that particular form of existence? What is the precise phenomenon which characterises fluidity? What is the definition of a fluid?* This is by no means an easy question, and considerable objections may be stated against any definition that has been given of it. Sir Isaac Newton says, that *a fluid is a body whose particles yield to the smallest impression, and by so yielding are easily moved among themselves.* It may be doubted whether this be sufficiently precise; what is meant by the *smallest impression?* and what is *easily moving!* Is there any precise degree of impression to which they do not yield; and do they oppose any resistance to motion? And a stronger objection may be made? It is not clear that a body so constituted will exhibit all the appearances which a body acknowledged to be fluid does really exhibit. Euler offers some very plausible reasons for doubting whether it will account for the horizontal surface, and the complete propagation of pressure through the fluid in every direction; and therefore prefers selecting *this last phenomenon*, the propagation of pressure *quæcumque versum*, as the characteristic of fluidity, because a body having this constitution (on whatever circumstances it may depend) will have every other observed property of a fluid. But this definition is hardly simple or perspicuous enough; and we think that the objections against Newton's more simple and intelligible definition are not unanswerable. Boscovich defines a fluid to be, *a body whose particles exert the same mutual forces in all directions;* and shows, that such particles must be indifferent, as to any position, with respect to each other. If no external force act on them, they will remain in every position, and will have no tendency to arrange themselves in one position rather than another; differing in this respect from the particles of solid, or soft, or viscid bodies; which require some force to change their respective positions, and which recover these positions again when but gently disturbed. He illustrates this distinction very beautifully, by comparing a parcel of balls thrown on quicksilver, and attracting each other, with a parcel of magnets in the same situation. The balls will stick together, but *in any position;* whereas the magnets will always affect a particular arrangement.

64 of the pressure and equilibrium of fluids, or hydrostatics.

When the characteristic phenomenon of fluidity has been selected, the philosopher proceeds to combine this property with gravity, and establishes the doctrines of HYDROSTATICS, or of the pressure and equilibrium of heavy fluids, the propagation of this pressure in every direction; and demonstrates the horizontality of surface assumed by all perfect fluids.

These doctrines and principles enable us to determine several very interesting circumstances respecting the mutual pressure of solids and fluids on each other; the pressures exerted on the bottoms and sides of vessels; the support and whole mechanism of floating bodies, &c.

65 of the motion of fluids, or hydraulics.

He then considers how fluids will move when their equilibrium of pressure is destroyed; and establishes the doctrines of HYDRAULICS, containing all the modifications of this motion, arising from the form of the vessels, or from the intensity or direction of the pressure which occasions it. And this subject is completed by the consideration of the resistance which fluids oppose to the motion of solid bodies through them, and the impulse on bodies opposed to their action.

These are very important matters, being the foundations of many mechanical arts, and furnishing us with some of our most convenient and efficacious powers for impelling machines. They are also of very difficult discussion, and are by no means completely investigated or established. Much remains yet to be done both for perfecting the theories and for improving the arts which depend on them.

Mechanical Philosophy. 66 The importance and difficulty of these branches of science.

It is evident, that on these doctrines depend the knowledge of the motions of rivers and of waves; the buoyancy, equilibrium, and stability of ships; the motion of ships through the waters; the action of the winds on the sails; and the whole arts of marine construction and seamanship.

There is another general form of tangible matter which exhibits very different phenomena, which are also extremely interesting; we mean that of VAPOUR. A vapour is a fluid; and all the vapours that we know are heavy fluids: they are therefore subject to all the laws of pressure and impulse, which have been considered under the articles HYDROSTATICS and HYDRAULICS. But they are susceptible of great compression by the action of external forces, and expand again when these forces are removed. In consequence of this compression and expansion, the general phenomena of fluidity receive great and important modifications; and this class of fluids requires a particular consideration. As air is a familiar instance, this branch of mechanical philosophy has been called PNEUMATICS.

67 The definition of vapour.

Under this head we consider the pressure of the atmosphere, and its effects, both on solid and fluid bodies. It produces the rise of waters or other fluids in pumps and syphons, and gives us the theory of their construction: it explains many curious phenomena of nature, such as the motions in the atmosphere, and their connection with the pressure of the air, and its effect on the barometer or weather-glass. Air, when in motion, is called *wind;* and it may be employed to impel bodies. The theory of its action, and of its resistance to moving bodies, are therefore to be considered in this place.

68 The doctrine of air, or pneumatics.

But besides their motions of progression, &c. such as we observe in winds, compressible or elastic fluids are susceptible of what may be termed *internal motion;* a kind of undulation, where the contiguous parts are thrown into tremulous vibrations, in which they are alternately condensed and rarefied; and these undulations are propagated along the mass of elastic fluid, much in the same way in which we observe waves to spread on the surface of water. What makes this an interesting subject of consideration is, that these undulations are the more ordinary causes of sound. A trembling chord, or spring, or bell, agitates the air adjoining to it: these agitations are propagated along the air, and by its intervention agitate the organ of hearing. The mechanism of these undulations has been much studied, and furnishes a very beautiful theory of musical harmony.

The philosopher examines the *law of compressibility* of air and other elastic fluids; and thus gets the knowledge of the constitution of the atmosphere, and of the action of those fluids when employed to impel solid bodies. Gunpowder contains an immense quantity of permanently elastic air, which may be set at liberty by inflammation. When this is done at the bottom of a piece of ordnance, it will impel a ball along the barrel, and

69 The compressibility of elastic fluids, and its consequences.

Mechanical Philoſophy and diſcharge it from the muzzle, in the ſame way that an arrow is impelled by a bow. And thus having diſcovered in what degree this air preſſes in proportion to its expanſion, we diſcover its action on the ball through the whole length of the piece, and the velocity which it will finally communicate to it. Here then is contained a theory of artillery and of mines.

70
Of the conversion of bodies into elastic fluids by fire.

Chemistry teaches us, that moſt bodies can be converted by fire into elastic fluids, which can be employed to act on other bodies in the way of preſſure or impulſe. Thus they come under the review of the mechanical philoſopher; and they have become intereſting by being employed as moving forces in ſome very powerful machines.

Theſe diſcuſſions will nearly exhaust all the general mechanical phenomena. There remain ſome which are much more limited, but furniſh very curious and important ſubjects of inveſtigation.

71
Of the phenomena of loadstone, or magnetiſm.

The phenomena exhibited between loadſtones or magnets and iron have long attracted attention; and the uſe to which the polarity of the loadſtone has been applied, namely, the directing the courſe of a ſhip through the pathleſs ocean, has rendered theſe phenomena extremely intereſting. They are ſpecified by the term **MAGNETISM**. Conſiderable progreſs has been made in the arrangement and generalization of them; but we have by no means been able hitherto to bring them all under one ſimple fact. The attention has been too much turned to the diſcovery of the ultimate cauſe of magnetiſm; whereas we ſhould have rather employed our ingenuity in diſcovering all the general laws, in the ſame manner as Kepler and Newton did with reſpect to the celeftial phenomena, without troubling themſelves with the cauſe of gravitation. Dr Gilbert of Colcheſter was the firſt who conſidered the magnetical phenomena in the truly philoſophical manner; and his treatiſe *De Magnete* may be conſidered as the firſt and one of the moſt perfect ſpecimens of the Baconian or inductive logic. It is indeed an excellent performance; and when we conſider its date, 1580, it is a wonder. *Æpinus's Tentamen Theoriæ Magnetiſmi* is a moſt valuable work, and contains all the knowledge which we have as yet of the ſubject.

72
Of electrical phenomena.

There is another claſs of mechanical phenomena which have a conſiderable affinity with the magnetical; we mean the phenomena called **ELECTRICAL**. Certain bodies, when rubbed or otherwiſe treated, attract and repel other bodies, and occaſion a great variety of ſenſible motions in the neighbouring bodies. Philoſophers have paid much attention to theſe appearances of late years, and eſtabliſhed many general laws concerning them. But we have not been more ſucceſſful in bringing them all under one fact, and thus eſtabliſhing a complete theory of them, than in the caſe of magnetiſm. Franklin and *Æpinus* are the authors who have been moſt ſucceſſful in this reſpect. Dr Franklin in particular has acquired great celebrity by his moſt ſagacious compariſon of the phenomena; which has enabled him to eſtabliſh a few general laws, almoſt as precise as thoſe of Kepler, and of equally extenſive influence. His diſcovery too of the identity of thunder and electricity has given an importance and dignity to the whole ſubject.

73
Theſe are not all mechanical.

There are many phenomena of electricity which cannot be called mechanical, and are of the moſt cu-

rious and intereſting kind. As theſe have little connection with any of the other great branches of phyſical ſcience, they have generally been conſidered in treatiſes of natural philoſophy; and along with inquiries into the original cauſe of electricity in general, continue to engage much of our attention.

Mechanical Philoſophy

The appearances which are preſented to us by our ſenſe of ſeeing form another claſs, which have always been conſidered as making a branch of natural philoſophy in all ſeminaries of learning. It does not, however, obviously appear, that they are mechanical phenomena. The intimate nature of light is ſtill a ſecret. Fortunately it is not neceſſary to be known to give us a very perfect theory of the chief phenomena. The general laws of optics are ſo few, ſo ſimple, and ſo precise, that our theories are perhaps more perfect here than in any other branch of phyſics; but theſe theories are as yet far removed from the rank of primary facts. Many unknown events happen before the phenomenon comes under the hands of the ordinary optician, ſo as to become the ſubjects of the ſimple laws of reflection and refraction. It may even be doubted, and has been doubted, whether the phenomena of optics are caſes of body in motion; whether all the lines which the optician draws are any thing but the directions along which certain *qualities* are exerted. The ſide of a ball which is next the candle may be bright and the other ſide dark, juſt as the ſide of a ball which is next the electrical globe is *minus* and the other ſide *plus*; and all this without any intervening medium. Apparition or viſibility may be a quality of a body, depending on the proximity and poſition of another body, without any thing between them, juſt as weight is; and this quality may be cognizable by our faculty of ſeeing alone, juſt as the preſſure of a heavy body is by our feeling alone.

74
Of the phenomena of viſion

75
It has been doubted whether light is corporeal.

The firſt thing which made it probable that mechanical philoſophy had any thing to do with the phenomena of optics, was the diſcovery of Mr Roemer, "that apparition was not inſtantaneous;" that ſome time elapſed between the illumination of a body and its being ſeen at a diſtance. He diſcovered, that it was not till 40 minutes after the ſun illuminated one of Jupiter's ſatellites that it was ſeen by an inhabitant of this globe. If therefore a ſun were juſt created, it would be 40 minutes before Jupiter would be illuminated by him, and 200 before the Georgian planet would be illuminated. Here then is motion. It is therefore highly probable that there is ſomething moved; but it is ſtill doubted whether this ſomething, which we call **LIGHT**, is a matter emitted from the ſhining body, and moving with great velocity, and acting on and affected by other bodies, in the various phenomena of optics; or whether it is a *cor ain ſtate* of a medium which is thus propagated, as we ſee that waves are propagated along the ſurface of water, or ſonorous undulations through the maſs of air, while the water or air itſelf is hardly moved out of its place. Either of theſe ſuppoſitions makes optics a legitimate branch of mechanical philoſophy; and it is the philoſopher's buſineſs to examine both by the received laws of motion, and ſee which of them gives conſequences which tally with the phenomena. This has been done; and we imagine that a complete incompatibility has been demonſtrated between the conſequences of the undula-

76
How optics came to be conſidered as a part of mechanical philoſophy.

77
The nature of light is ſtill undetermined.

Mechanical Philosophy

dulations of an elastic medium, and the phenomena of optics; while the consequences of the other or vulgar notion on this subject are perfectly consistent with mechanical laws. There are some things in this hypothesis very far beyond our power to conceive distinctly; but they are all similar in this respect to many facts acknowledged by all; and there is no phenomenon that is inconsistent with the legitimate consequences of the hypothesis. This gives it great probability; and this probability is confirmed by many chemical facts, and by facts in the vegetable oecomy, which give strong and almost undeniable indications of light being a body capable of a chemical union with the other ingredients of sublunary bodies, and of being afterwards set at liberty under its own form, as the cause or medium of vision.

78 But this does not affect the science of optics.

But these are questions similar to those about the cause of gravity, and totally unnecessary for establishing a complete theory of the optical phenomena, for explaining the nature of vision, the effects of optical instruments, the cause of colours, the phenomena of the rainbow, halos and periheliums, &c. &c. &c. Only all this theory is unconnected with the principles called mechanical.

79 The probable increase of the above extensive field of observation.

Such is the field of observation to the mechanical philosopher of the present day. We may hope to extend it, and by degrees apply its doctrines even to the unseen motions which take place in chemistry and physiology. But we must, in the first place, perfect our knowledge and description of the sensible motions and actions of bodies. Those of fluids still demand much investigation; and till these are thoroughly understood, it is not time to attempt penetrating further into the recesses of nature.

80 Investigation of the law that action is always equal and opposite to reaction.

In the prosecution of this study, it is found that every change which can be observed in the state of a body, with respect to motion by the action of another body, is accompanied by an equal and opposite change in the state of that other body. Thus in the phenomena of gravitation, it is observed that the deflections of the sun and planets are mutual. The same thing is observed in the actions of magnets on each other and on iron; it is also observed in the attractions and repulsions of electrical bodies; and it also obtains in all the phenomena of impulse and of corporeal pressure. It is therefore an universal law of motion, that *action is always equal and opposite to reaction*: but this must be considered merely as a matter of fact, a contingent law of nature, like that of gravitation. The contrary is perfectly conceivable, and involves no contradiction. That this is so, is evident from the proceedings of philosophers, who in every new case make it their business to discover by experiment whether this law was observed or not. It was among the last discoveries made by Sir Isaac Newton in his examination of the celestial motions. This being the case, it should never be assumed as a principle of reasoning till its operation has been ascertained by observation. It has been owing to this improper procedure that much false reasoning has been introduced into mechanical philosophy, and particularly into the theory of impulsion or the communication of motion by impulse. In considering this subject, a term has been introduced which has occasioned much wrangling and misconception; we mean the term *INERTIA*. It serves indeed to abbreviate language, but it has often misled the judge-

81 The term inertia has occasioned much wrangling and misconception on this subject.

ment. When used with cautious attention to every circumstance, it expresses nothing but the necessity of a cause to the production of any effect: but it is generally used as expressing a quality inherent in matter, by which it *resists* any change of state, or by which it maintains its present state. Matter is said to be inert; and as every thing which changes the motion of a body is called a *force*, and as this inertia of A is supposed to change the motion of B, it is called *vis inertiae*; and yet matter is said to be indifferent as to motion or rest, and to be inactive. These are surely very incongruous expressions. This obscure discourse has arisen from the poverty of all languages, which are deficient in original terms, and therefore employ figurative ones. Force, action, resistance, are all appropriated terms related to our own exertions; and some resemblance between the external effects of these exertions and the effects of the connecting qualities of natural bodies, has made us use them in our disquisitions on these subjects. And as we are conscious that, in order to prevent our being pushed by another from our place, we must resist, exerting force; and that our resistance is the reason why this other man has not accomplished his purpose, we say, that the quiescent body resists being put in motion, and that its inertia is discovered by the diminution made in the motion of the impelling body: and upon the authority of this *vis inertiae* as a first principle, the phenomena of impulsion are explained, and the law of equal action and reaction is established.

But all this procedure is in contradiction to the rules of inductive logic; and the obscurity and confusion which has arisen from this original misconception the consequent incongruity of language, and the awkward attempts that have been made to botch and accommodate it to the real state of things, have occasioned a dispute, and the only dispute, in natural philosophy which has not yet been settled, and never can be settled, while such misconceptions are allowed to remain.

If the word *inertia* be taken as expressing, not a quality of matter, but a law of human judgment respecting matter, as expressing our necessity of inferring the agency of a moving force whenever we observe a change of motion, all difficulties will vanish, and the equality of action and reaction will be inferred, as it should be, from the phenomena of collision. There will be inferred a *vis insita corpori impellenti*, not *quæ moventi*, but *quæ corporis*; and this inference will carry us through all the mysteries of corporeal action, as it conducted Sir Isaac Newton in his great researches.

82 Its proper meaning, with an example.

Let us just consider how we reason in a new case. Let A and B be two magnets fastened on the ends of two long wooden laths *AE*, *BF*, which turn horizontally on pivots *C*, *D*, like compass needles, with their north poles fronting each other, 12 inches apart; and let A be pushed towards B, so that it would move uniformly with the velocity of two inches in a second. The phenomena which have been observed are as follow: A will gradually diminish its velocity; and when it has advanced about nine inches, will stop completely. B, in the mean time, will gradually acquire motion; and

when

Mechanical when it has advanced about nine inches, will have a **Philosophy** velocity of about two inches per second, with which it will continue to move uniformly. Now what is inferred from these phenomena? Because the motion of A is gradually retarded, we infer that a retarding force, that is, a force in the direction BA has acted on it. And since this would not have happened if B had not been there, and always happens when B is there, we infer that B is either its cause or the occasion of its action. The vulgar say that B repels A; so say the dynamists. The abettors of invisible fluids say, that a stream of fluid issuing from B impels A in the opposite direction. All naturalists agree in saying, that an active force connected with B has destroyed the motion of A, and consider this curious phenomenon as the indication and characteristic of a discovery. The same inference is made from the motion produced in B: it is considered by all as effected by a force exerted or occasioned by the presence of A; and the dynamists and the vulgar say that A repels B. And both parties conclude, from the equal changes made on both bodies, that the changing forces are equal: here acknowledging, that they observe an equality of action and reaction; and they add this to the other instances of the extent of this law of motion.

All this while no one thinks of the inertia or inactivity of B, but, on the contrary, conclude this to be a curious instance of its activity; and most people conclude that both bodies carry about with them a *vis insita* both when at rest and when in motion.

83 It is doubtful whether actual contact has ever been observed.
 If other phenomena give unquestionable evidence that, in ordinary collisions, there is the same changes of motion, produced without mathematical contact, the same inferences must be drawn; and a scrupulous naturalist will doubt whether contact should make any change in our reasonings on the subject, and whether actual contact ever has been or can be observed. He will also be convinced, that while this is the general, or perhaps universal, process of nature in producing motion by impulse, all explanations of the action of bodies *e distant*, by the intervention of ethers and other invisible fluids, are nothing but multiplying the difficulties; for in place of one fact, the approach of one magnet (for instance) to another, they substitute millions of unseen impulses, each of which equally needs an explanation. And if this fluid be supposed to produce its effects by any *peculiarity* in its constitution, as in the case of Newton's elastic ether proposed by him to explain gravitation, the hypothesis substitutes, in the most unqualified manner, millions of similar phenomena for the one to be explained; for there is the same want of a second fluid in order to produce that mutual recess of the particles of the ether which constitutes its elasticity.

84 The folly of supposing intervening ethers, &c.
85 The quality of bodies whereby they affect other bodies is inscrutable by us.
 And this seems to be the limit to our inquiries into all the classes of natural phenomena. We find the masses or the particles of matter endued in fact with qualities which affect the state of other particles or masses, at smaller or at greater distances from each other according to certain general rules or laws. This ultimate step in the constitution of things is inscrutable by us. It is arrogance in the highest degree for us to say, that because we do not comprehend how there is inherent in a body any quality by which another body may be affected at any distance from it,

therefore no such quality is possible. It is no less so to say, that matter has no active property but that of moving other matter by impulse; and that because it may be so moved, and also by the agency of our own minds, therefore, when it is not moved by impulse, it is moved by minds. The same almighty *FIAT* which brought a particle of matter into existence could bring those qualities equally into existence; and the *how* in both is equally beyond our comprehension.

But, on the other hand, we must guard against the incautious resting on this consideration as a stop to further inquiry. There may be species of matter possessed of the mechanical powers, and which notwithstanding is not cognisable by our senses. All the properties of matter are not known to a person who is both deaf and blind; and beings possessed of more senses may perceive matter where we do not; and many phenomena may really be produced by the action of intervening matter, which we, from indolence or from haste, ascribe to the agency of inherent forces. The industry of philosophers has already discovered intermedia in some cases. It is now certain that air is the conveyer of sound, and it is almost certain that there is such a thing as light. Let us therefore indulge conjectures of this kind, and examine the conjectures by the received laws of motion, and reject them when we find the smallest inconsistency; and always keep in mind that even the most coincident with the phenomena is still but a possibility.

We may conclude the whole of these observations with the remark, that these questions about the activity or inactivity of matter are not physical, but metaphysical. Natural philosophy, it is true, commonly takes it for granted that matter is wholly inactive; but it is not of any moment in physics whether this opinion is true or false; whether matter is acted on according to certain laws, or whether it acts of itself according to the same laws, makes no difference to the natural philosopher. It is his business to discover the laws which really obtain, and to apply these to the solution of subordinate phenomena: but whether these laws arise from the nature of some agent external to matter, or whether matter itself is the agent, are questions which may be above his comprehension, and do not immediately concern his proper business.

The account we have now given of natural philosophy points out to us in the plainest manner the way in which the study must be prosecuted, and the helps which must be taken from other branches of human knowledge.

The causes, powers, forces, or by whatever name we choose to express them, which produce the mechanical phenomena of the universe, are not observed, and are known to us only in the phenomena themselves. Our knowledge of the mechanical powers of nature must therefore keep pace with our knowledge of the motions, and indeed is nothing different from it. In order to discover and determine the forces by which the moon is retained in her orbit round the earth, we must know her motions. To a terrestrial spectator she appears to describe an ellipse, having the earth in one focus; but, in the mean time, the earth is carried round the sun, and the moon's real path, in absolute space, is a much more complicated figure. Till we know this figure, and the variations in the velocity with

Mechanical
Philosophy

86
 This should not, however, further inquire.

87
 These observations are not physical, but metaphysical.

88
 The above account points out the best method of study.

89
 This method further explained and exemplified.

Mechanical
Philosophy

of the ce-
lestial mo-
tions.

with which it is described, we know nothing of the forces which actuate the moon in her orbit.

When Newton says that the forces by which she is retained in this elliptical orbit are directed to the earth, what does he mean? Only this, that the deflection from that uniform rectilinear motion which she would otherwise have performed are always in this direction. In like manner, when he says that these forces are inversely proportionate to the squares of her distances from the earth, he only means that the deflections made in equal times in different parts of her motion are in this proportion. These deflections are considered as the characteristics and measures of the forces. We imagine that we have made all plain when we call this indicated cause a *tendency* to the earth; but we have no notion of this tendency to the earth different from the approach itself. This word tendency, so fashionable among the followers of Sir Isaac Newton, is perverted from its pure and original sense. *Tendere versus solem*, is, in the language of Rome, and also of Newton, *to go towards the sun*; but we now use the words *tend, tendency*, to signify, not the *approach*, but the *cause* of this approach. And when called upon to speak still plainer, we desert the safe paths of plain language, and we express ourselves by metaphor, speaking of *nisus, comatus sese mutuo accedende, vis centri-peta*, &c. When these expressions have become familiar, the original sense of the word is forgotten, and we take it for granted that the words never had another meaning; and this metaphor, sprung from the poverty of language, becomes a fruitful source of misconception and mistake. The only way to secure ourselves against such mystical notions as are introduced by these means into philosophy, is to have recourse to the way in which we acquire the knowledge of these fancied powers; and then we see that their names are only names for phenomena, and that universal gravitation is only an universal mutual approach among the parts of the solar system.

The absurd-
ity of rea-
soning à
priori.

There is one case in which we fondly imagine that we know the cause independent of the effect, and that we could have predicted the phenomenon *à priori*: we mean the case of impulse: and hence it is that we are so prone to reduce every thing to cases of impulsion, and that we have fallen upon all these subtleties of ethers and other subtle fluids. But we might have saved ourselves all this trouble: for after having, by much false reasoning and gratuitous assumptions, shown that the phenomenon in question *might have been produced* by impulse, we are no nearer our purpose, because that property by which matter in motion puts other matter in motion, is known to us only *by* and *in* the effect.

92
We know
nothing of
the imme-
diate causes
of motions
except by a
knowledge
of the mot-
ions them-
selves.

The fair and logical deduction from all this is, that we must not expect any knowledge of the powers of nature, the immediate causes of the motions of bodies, but by means of a knowledge of the motions themselves; and that every mistake in the motions is accompanied by a similar mistake in the causes. It is impossible to demonstrate or explain the gravitation of the planets to him who is ignorant of the properties of the ellipse, or the theory of gunnery to him who does not know the parabola.

A notion has of late gained ground, that a man may become a natural philosopher without mathema-

tical knowledge; but this is entertained by none who have any mathematics themselves; and surely those who are ignorant of mathematics should not be sustained as judges in this matter. We need only appeal to fact. It is only in those parts of natural philosophy which have been mathematically treated, that the investigations have been carried on with certainty, success, and utility. Without this guide, we must expect nothing but a school-boy's knowledge, resembling that of the man who takes up his religious creed on the authority of his priest, and can neither give a reason for what he imagines that he believes, nor apply it with confidence to any valuable purpose in life. We may read and be amused with the trifling or vague writings of authors of this class; but we shall not understand, nor profit by the truths communicated by a Newton, a D'Alembert, or De la Grange.

These observations, on the other hand, show us the nature of the knowledge which may be acquired, and the rank which natural philosophy holds among the sciences.

Motions are the real and only objects of our observation, the only subjects of our discussion. In motion is included no ideas but those of space and time, the subjects of pure mathematical disquisition. As soon, therefore, as we have discovered the fact, the motion, all our future reasonings about this motion are purely mathematical, depending only on the affections of figure, number, and proportion, and must carry along with them that demonstration and irresistible evidence which is the boast of that science. To this are we indebted for that accuracy which is attained, and the progress which has been made in some branches of mechanical philosophy; for when the motions are distinctly and minutely understood, and then considered only as mathematical quantities, independent of all physical considerations, and we proceed according to the just rules of mathematical reasoning, we need not fear any intricacy of combination or multiplicity of steps; we are certain that truth will accompany us, even though we do not always attend to it, and will emerge in our final proposition, in the same manner as we see happen in a long and intricate algebraic analysis.

Mechanical philosophy, therefore, which is cultivated in this way, is not a system of probable opinions, but a *dispositio acurata*, a demonstrative science. To possess it, however, in this form, requires considerable preparation. The mere elements of geometry and algebra are by no means sufficient. Newton could not have proceeded *sine "sua mathefi facem preferente;"* and in creating a new science of physics, he was obliged to search for and discover a new source of mathematical knowledge. It is to be lamented that the taste for the mathematical sciences has so prodigiously declined among philosophers of late years; and that Britain, which formerly took the lead in natural philosophy, should now be the country where they are least cultivated. Few at present know more than a few elementary doctrines of equilibrium; while, on the continent, we find many authors who cultivate the Newtonian philosophy with great assiduity and success, and whose writings are consulted as the fountains of knowledge by all those gentlemen who have occasion to employ the discoveries in natural philosophy in the arts of life. It is

97
Notwithstanding the amplest encouragement from the crown.

to the foreign writers that we have recourse in our seminaries, even for elementary treatises; and while the continent has supplied us with most elaborate and useful treatises on various articles in physical astronomy, practical mechanics, hydraulics, and optics, there has not appeared in Britain half a dozen treatises worth consulting for these last forty years; and this notwithstanding the great munificence of the present sovereign, who has given more liberal patronage to the cultivators of mathematical philosophy, and indeed of science in general, than any prince in Europe. The magnificent establishments of Louis XIV. originated from his insatiable ambition and desire of universal influence, directed by the sagacious Colbert. And his patronage being exerted according to a regular plan in the establishment of pensioned academies, and in procuring the combined efforts of the most eminent of all countries, his exertions made a conspicuous figure, and filled all Europe with his eulogists. But all this was done without the smallest self-denial, or retrenchment of his own pleasures, the expences being furnished out of the public revenues of a great and oppressed nation; whereas the voyages of discovery, the extensive observations and geodetical operations in Britain, and the numberless unheard-of pensions and encouragements given to men of science and activity, were all furnished out of the revenues of the prince in whose reign they have been accomplished. It is still doubtful, however, whether a taste for the mathematical sciences is likely to be revived in Britain, and the eyes of Europe once more directed thither for instruction and improvement as has been formerly the case. The present indeed seems a most favourable era, while the amazing advances in manufactures of every kind seem to call aloud for the assistance of the philosopher. What pleasure would it have given to Newton or Halley to have seconded the ingenious efforts of a Watt, a Bolton, a Smeaton, an Arkwright, a Dollond? and how mortifying is it to see them indebted to the services of a Belidor, a Bossut, a Clairaut, a Boscovich?

We hope to be pardoned for this digression, and return to our subject.

It appears from what has been said, that mechanical philosophy is almost wholly a mathematical study, and that it is to be successfully prosecuted only under this form: but in our endeavours to initiate the young beginner, it will be often found to require more readiness of thought than can generally be expected for keeping the mind engaged in such abstract speculations. The object presented to the mind is not readily apprehended with that vivacity which is necessary for enabling us to reason upon it with clearness and steadiness, and it would be very desirable to have some means of rendering the conception more easy, and the attention more lively. This may be done by exhibiting to the eye an experiment, which, though but a single fact, gives us a sensible object of perception, which we can contemplate and remember with much more steadiness than any mere creature of the imagination. We could, by an accurate description, give such a conception of a room that the hearer should perfectly comprehend our narration of any occurrence in it: but one moment's glance at the room would be infinitely better. It is usual therefore to employ ex-

periments to assist the imagination of the beginner; and most courses of natural philosophy are accompanied by a series of such experiments. Such experiments, connected by a slight train of argumentative discourse, may even serve to give a notion of the general doctrines, sufficient for an elegant amusement, and even tending to excite curiosity and engage in a serious prosecution of the study. Such are the usual courses, which go by the name of experimental philosophy; but this is a great misapplication of the term; such courses are little more than *illustrations* of known doctrines by experiments.

EXPERIMENTAL PHILOSOPHY is the investigation of general laws, as yet unknown, by experiment; and it has been observed, under the article PHILOSOPHY, that this is the most infallible (and indeed the safest) way of arriving at the knowledge of them. This is the *Novum Organum Scientiarum* strongly recommended by Lord Bacon. It was new in his time, though not altogether without example; for it is the procedure of nature, and is followed whenever curiosity is excited. There was even extant in his time a very beautiful example of this method, viz. the Treatise of the Loadstone, by Dr Gilbert of Colchester; a work which has hardly been excelled by any, and which, when we consider its date, about the year 1580, is really a wonderful performance.

The most perfect model of this method is the Optics of Sir Isaac Newton. Dr Black's Essay on Magnesia is another very perfect example. Dr Franklin's Theory of Electricity is another example of great merit. That the investigation is not complete, nor the conclusions certain, is not an objection. The method is without fault; and a proper direction is given to the mind for the experiments which are still necessary for establishing the general laws.

It were much to be wished that some person of talents and of extensive knowledge would give a treatise on the method of inquiry by experiment. Although many beautiful and successful examples have been given as particular branches of inquiry, we have but too many instances of very inaccurate and inconclusive investigations. Experiments made at random, almost without a view, serve but little to advance our knowledge. They are like shapeless lumps of stone, merely detached from the rock, but still wanting the skill of the builder to select them for the different purposes which they may chance to serve; while well contrived experiments are blocks cut out by a skilful workman, according as the quarry could furnish them, and of forms suited to certain determined uses in the future edifice. Every little series of experiments by Margraaf terminates in a general law, while hardy any general conclusion can be drawn from the numberless experiments of Pott. Lord Bacon has written much on this subject, and with great judgment and acuteness of distinction; but he has exceeded in this, and has fatigued his readers by his numerous rules; and there is in all his philosophical works, and particularly in this, a quaintness and affectation that greatly obscure his meaning, so that this most valuable part of his writings is very little read.

A formidable objection has been made to this method of inquiry. Since a physical law is only the

Experiments are however necessary to insure the attention of young minds.

Experimental
Philosophy

expression of a general fact, and is established only in consequence of our having observed a similarity in a great number of particular facts; and since the great rule of inductive logic is to give the law no greater extent than the induction on which it is founded—how comes it that a few experiments must be received as the foundation of a general inference? This has been answered in very general terms in the article PHILOSOPHY. But it will be of use to consider the subject a little more particularly. Our observations on this subject are taken from the dissertation on evidence by Dr Campbell in his *Philosophy of Rhetoric*.

IC3
The objection answered, with examples showing the nature and certainty of this mode of inquiry.

An attentive consideration of the objects around us, will inform us that they are generally of a complicated nature, not only as consisting of a complication of those qualities of things called accidents, such as gravity, mobility, colour, figure, solidity, which are common to all bodies; but also as consisting of a mixture of a variety of substances, very different in their nature and properties; and each of these is perhaps compounded of ingredients more simple.

Moreover, the farther we advance in the knowledge of nature, we find the more reason to be convinced of her constancy in all her operations. Like causes have always produced like effects, and like effects have always been preceded by like causes. Inconstancy sometimes appears in Nature's works at *first sight*; but a more refined experience shows us that this is but an appearance, and that there is no inconstancy: and we explain it to our satisfaction in this way.

Most of the objects being of a complicated nature, we find, on an accurate scrutiny, that the effects ascribed to them ought often to be solely ascribed to one or more of these component parts, while the others either do not contribute to them, or hinder their production; and the variety of nature is so great, that hardly any two individuals of the same species are in every respect like any other. On all these accounts we expect dissimilarities in the phenomena accompanying perfectly similar treatment of different subjects of the same kind; but we find, that whenever we can be assured that the two substances are perfectly alike, the phenomena arising from similar treatment are the same: and long and extensive observation teaches us, that there are certain circumstances which insure us in the perfect similarity of constitution of some things. Whenever we observe the effect of any natural agent on one, and but one, of these, we invariably expect that the same will be produced on any other.

Should a botanist meet with a plant new to him, and observe that it has seven monopetalous flowers, he will conclude with the utmost confidence that every plant of this species will have monopetalous flowers; but he will not suppose that it will have seven, and no more than seven, flowers. Now these two facts seem to have no difference to warrant such a difference in the conclusion; which may therefore seem capricious, since there is but one example of both.

But it is not from this example only that he draws the conclusion. Had he never before taken notice of any plant, he would not have reasoned at all from these remarks. But his mind runs immediately from this unknown species to all the known species of this genus, and to all the genera of the same order; and having experienced in the *figure* of the flower an

uniformity in every species, genus, and order, which admits of no exception, but, in the *number* of flowers, a variety as boundless as are the circumstances of soil, climate, age, and culture, he learns to mark the difference, and draws the abovementioned conclusions. Thus we learn, that *perfect* uniformity is not to be expected in any instance whatever, because in no instance is the simplicity of constitution sufficiently great to give us assurance of perfect uniformity in the circumstances of the case; and the utmost that our experience can teach us is a quick discrimination of those circumstances which produce the occasional varieties.

The nearer that our investigations carry us to the knowledge of *elementary* natures, the more are we convinced by general experience of the uniformity of the operations of real elements; and although it may perhaps be impossible for us ever to arrive at the knowledge of the simplest elements of any body, yet when any thing *appears* simple, or rather so exactly uniform, as that we have invariably observed it to produce similar effects on discovering any *new* effect of this substance, we conclude, from a general experience of the efficient, a like constancy in the energy as to the rest. Fire consumes wood, melts lead, and hardens clay. In these instances it acts uniformly, but not in these only. We have always found, that whatever of any species is consumed by it in one instance, has been consumed by it on trial at any time. If therefore a trial be made for the first time of its influence on any particular substance, he who makes it is warranted to conclude that the effect, whatever it may be, is a faithful representative of its effects on this substance in all past and future ages. This conclusion is not founded on this single instance, but upon this instance combined with the general experience of the regularity of this element in its operations.

This general conclusion, therefore, drawn from one experiment, is by no means in opposition to the great rule of inductive logic, but, on the contrary, it is the most general and refined application of it. General laws are here the real subject of consideration; and a law still more general, *viz. that nature is constant in all its operations*, is the inference which is here applied as a principle of explanation of a phenomenon which is itself a general law, *viz. that nature is constant in this operation*.

The foundation of this general inference from one experiment being so firmly established, it is evident that experiments must be an infallible method of attaining to the knowledge of nature; and we need only be solicitous that we proceed in a way agreeable to the great rule of inductive logic; that is, the subject must be cleared of every accidental and *unknown* circumstance, and put into a situation that will reduce the interesting circumstance to a state of the greatest possible simplicity. Thus we may be certain that the event will be a faithful representative of every similar case: and unless this be done in the preparation, nothing can result from the most numerous experiments but uncertainty and mistakes.

The account which has been given of mechanical philosophy would seem to indicate that experiment was not of much use in the farther prosecution of it. The two laws of motion, with the assistance of mathematics, seem fully adequate to the explanation of every

Experimental
Philosophy

IC4
Mathematics do not supersede the use of experiment.

Experi-
mental
Philosophy

Experi-
mental
Philosophy

phenomenon; and so they are to a *certain degree*. But this degree is as yet very limited. Our mathematical knowledge, great as it is in comparison with that of former times, is still insufficient for giving accurate solutions even of (comparatively speaking) very simple questions. We can tell, with the utmost precision, what will be the motions of two particles of matter, or two bodies, which act on each other with forces proportioned to the squares of the distances inversely; but if we add a third particle, or a third body, acting by the same law, the united science of all Europe can only give an approximation to the solution.

the phenomena. The patient and sagacious Newton has repeatedly failed in his attempts to determine what is the *absolute velocity* of water issuing from a hole in the bottom of a vessel when urged by its weight alone, and the attempts of the others have hardly succeeded better. Experiment is therefore absolutely necessary on this head.

105
Experi-
ment is of-
ten the
only re-
source.

What is to be done then in the cases which come continually before us, where millions of particles are acting at once on each other in every variety of situation and distance? How shall we determine, for instance, the motion of water through a pipe or sluice when urged by a piston or by its own weight? what will be its velocity and direction? It is impossible, in the present state of mathematical knowledge, to tell with any precision or certainty. And here we must have recourse to experiment. But if this be the case, must the experiment be made in every possible variety of situation, depth, figure, pressure? or is it possible to find out any general rules, founded on the general laws of motion, and rationally deduced from them? Or, if this cannot be accomplished, will experiment itself furnish any general coincidences which show such mutual dependences, that we may consider them as indications of general principles, though subordinate, complicated, and perhaps inscrutable? This can be discovered by experiment alone.

Those who have aimed at the discovery of *rules*, purely experimental on this subject, have also been pretty successful; and the Chevalier Buat has, from a comparison of an immense variety of experiments made by himself and various authors, deduced an empirical rule, which will not be found to deviate from truth above one part in ten in any case which has yet come to our knowledge.

This instance may serve to show the use of experiments in mechanical philosophy. It is proper in all cases by way of illustration; and it is absolutely necessary in most, either as the foundation of a characteristic of a particular class of phenomena, or as argument in support of a particular doctrine. Hydrostatics, hydraulics, pneumatics, magnetism, electricity, and optics, can hardly be studied in any other way; and they are at present in an imperfect state, and receiving continual improvement by the labours of experimental philosophers in all quarters of the world.

106
Accurate
experi-
ments can-
not always
be made.

The attention of philosophers has been directed to each of these three chances, and considerable progress has been made in them all. Numerous experiments have been made, almost sufficient to direct the practice in many important cases, without the help of any rule or principle whatever. But there are many cases, and these of by far the greatest importance, such as the motion of a ship impelled by the winds, resisted by the water, and tossed by the waves, where distinct experiments cannot be made.

Having in the preceding paragraphs given a pretty full enumeration of the different subjects which are to be considered in the study of natural philosophy, it will not be necessary to spend much time in a detail of the advantages which may reasonably be expected from a successful prosecution of this study. It stands in no need of panegyric: its intimate connection with the arts gives it a sufficient recommendation to the attention of every person. It is the foundation of many arts, and it gives liberal assistance to all. Indebted to them for its origin and birth, it has ever retained its filial attachment, and repaid all their favours with the most partial affection.

of philoso-
phy.

107
Example of
the necessi-
ty of experi-
ment.

Newton, Bernoulli, D'Alembert, and others have laboured hard to deduce from the laws of motion rules for determining what may be called the *average* motion of water in these circumstances, without attempting to define the path or motion of any individual particle: and they have actually deduced many rules which have a great degree of probability. It may here be asked, why do you say *probability*? the rules, as far as they go, should be *certain*. So they are: they are strict deductions from their premises. But the premises are only *suppositions*, of various degrees of probability, assumed in order to simplify the circumstances of the case, and to give room for mathematical reasoning; therefore these deductions, these rules, must be examined by experiment. Some of the suppositions are such as can hardly be refused, and the rules deduced from them are found to tally precisely with the phenomena. Such is this, "that the velocities of issuing water in similar circumstances are in the subduplicate ratio of the pressures." And this rule gives a most important and extensive information to the engineer. Other suppositions are more gratuitous, and the rules deduced from them are less coincident with

To this science the navigator must have recourse for that astronomical knowledge which enables him to find his place in the trackless ocean: and although very small scraps of this knowledge are sufficient for the mere pilot, it is necessary that the study be prosecuted to the utmost by some persons, that the unlearned pilot may get that scanty pittance which must direct his routine. The few pages of tables of the sun's declination, which he uses every day to find his latitude, required the successive and united labours of all the astronomers of Europe to make them tolerably exact: and in order to ascertain his longitude with precision, it required all the genius of a Newton to detect the lunar irregularities, and bring them within the power of the calculator; and, till this was done, the respective position of the different parts of the earth could not be ascertained. Vain would have been the attempt to do this by geodetical surveys independent of astronomical observation. It is only from the most refined mechanics that we can hope for sure principles to direct us in the construction and management of a ship, the boast of human art, and the great means of union and communication between the different quarters of the globe.

109
In naviga-
tion.

A knowledge of mechanics not much inferior to this is necessary for enabling the architect to execute

mental
Philosophy

111
In gunnery
and other
engines,
&c.

some of his greatest works, such as the erection of domes and arches, which depend on the nicest adjustment of equilibrium. Without this he cannot unite economy with strength; and his works must either be clumsy masses or flimsy shells.

The effects of artillery cannot be understood or secured without the same knowledge,

The whole employment of the engineer, civil or military, is a continual application of almost every branch of mechanical knowledge; and while the promises of a Smeaton, a Watt, a Belidor, may be confided in as if already performed, the numberless failures and disappointments in the most important and costly projects show us daily the ignorance of the pretending crowd of engineers.

The microscope, the steam engine, the thunder-rod, are presents which the world has received from the natural philosopher; and although the compass and telescope were productions of chance, they would have been of little service had they not been studied and improved by Gilbert, Halley, and Dollond.

But it is not in the arts alone that the influence of natural philosophy is perceived: it lends its aid to every science, and in every study.

112
In law,

It is often necessary to have recourse to the philosopher in disputes concerning property; and many examples might be given where great injustice has been the consequence of the ignorance of the judges. Knowledge of nature might have prevented many disgraceful condemnations for forgery.

113
In history,

The historian who is ignorant of natural philosophy easily admits the miraculous into his narrations, accompanies these with his reflections, draws consequences from them, and fills his pages with prodigies, fables, and absurdity.

114
In medi-
cine,

It is almost needless to speak of the advantages which will accrue to the physician from this study. So close is the connection between it and medicine, that our language has given but one name to the naturalist and to the medical philosopher. Indeed, the whole of his study is a close observation of the laws of material nature, in order to draw from them precepts to direct his practice in the noble art of healing. During the immaturity of general knowledge, while natural philosophy was the only study which had acquired any just pretension to certitude either in its principles or method of investigation, the physicians endeavoured to bring the objects of their study within its province, hoping by this means to get a more distinct view of it; and they endeavoured to explain the abstruse phenomena of the animal functions by reducing them all to motions, vibrations, collisions, impulses, hydrostatic and hydraulic pressures and actions, with which the mechanical philosophers were so ardently occupied at that time. But unfortunately their acquaintance with nature was then very limited, and they were but little habituated to the rules of just reasoning; and their attempts to explain the economy of animal life by the laws of mechanics did them but little service either for the knowledge of diseases or of the methods of cure. The mechanical theories of medicine, which had considerable reputation about the end of last century, were many of them very ingenious, and had an imposing appearance of symmetry and connection; but are now forgotten, having all been formed on the narrow sup-

position that matter was subject only to mechanical laws.

But the discovery of error diminishes the chance of again going wrong, especially when the cause of error has been discovered, and the means pointed out of detecting the mistakes; and the vital principle must combine its influence with, or operate on, the properties of rude matter. It appears therefore evident that a knowledge of the mechanical laws of the material world is not only a convenient, but a necessary, accomplishment to the physician. We are fully justified in this opinion, by observing medical authors of the present day introducing into medicine theories borrowed from mechanical philosophy, which they do not understand, and which they continually misapply. Appearance of reasoning frequently conceals the errors in principle, and seldom fails to mislead.

Experi-
mental
Philosophy

115
In religion,

But there is no class of men to whom this science is of more service than to those who hold the honourable office of the teachers of religion. Their knowledge in their own science, and their public utility, are prodigiously hurt by ignorance of the general frame and constitution of nature; and it is much to be lamented that this science is so generally neglected by them, or considered only as an elegant accomplishment: nay, it is too frequently shunned as a dangerous attainment, as likely to unhinge their own faith, and taint the minds of their hearers. We hope, however, that few are either so feebly rooted in the belief of the great doctrines of religion as to fear this, or of minds so base and corrupted as to adopt and inculcate a belief which they have any suspicion of being ill-founded. But many have a sort of horror at all attempts to account for the events of nature by the intervention of general causes, and think this procedure derogatory to the Divine nature, and inconsistent with the doctrine of his particular providence; believing, that "a sparrow does not fall to the ground without the knowledge of our heavenly Father." Their limited conceptions cannot perceive, that, in forming the general law, the Great Artist did at one glance see it in its remotest and most minute consequence, and adjust the vast assemblage so as completely to answer every purpose of His providence. There never was a more eager inquirer into the laws of nature, or more ardent admirer of its glorious Author, than the Hon. Robert Boyle. This gentleman says, that he will always think more highly of the skill and power of that artist who should construct a machine, which, being once set a going, would of itself continue its motion for ages, and from its inherent principles continue to answer all the purposes for which it was first contrived, than of him whose machine required the continual aid of the hand which first constructed it. It is owing to great inattention that this aversion to the operation of secondary causes has any influence on our mind. What do we mean by the introduction of secondary causes? How do we infer the agency of any cause whatever? Would we ever have supposed any cause of the operations of nature, had they gone on without any order or regularity? Or would such a chaos of events, any more than a chaos of existences, have given us any notion of a forming and directing hand? No surely. We see the hand of God in the regular and unvaried course of nature, only because it is regular and unvaried. The philo-

vantages of
philosophy.

pher expresses this by saying, that the phenomena proceed by unalterable laws. Greatly mistaken therefore are they who think that we supersede the existence of mind and of providence when we trace things to their causes. A physical law being an unvaried fact, is an indication, and the strongest possible indication, of an unerring mind, who is incapable of change, and must do to day what He always did: for to change is to deviate from what is best*. The operations of unerring mind will therefore be regular and invariable. Physical laws, therefore, or secondary causes, are the best proofs of unerring wisdom. Such regularity of conduct is universally considered as indications of wisdom among men. The wise man is known by the constancy of his conduct, while no man can depend on the future conduct of a fool.

And what astonishing evidences of wisdom do we not observe in the general laws of the material world? They will ever be considered by the intelligent philosopher as the most glorious display of inconceivable wisdom, which has been able, by means so few and so simple, to produce effects which by their grandeur astonish our feeble understandings, and by their inexhaustible variety elude all possibility of enumeration.

While the teachers of religion remain ignorant of the beautiful laws of nature, the great characteristics of the wisdom and goodness of the Almighty Creator, their hearers are deprived of much sublime pleasure; God is robbed of that praise which he would have received from an enlightened people; and the only worship he receives is tainted with mean notions of his attributes, and groundless fears of his power.

Let not our minds be haunted with fear of the pernicious effect, of philosophy, in consequence of the foolish extremes into which pretended philosophers have lately run, they are but the irregular effusions of the moment, probably arising from the present perturbed state of some of the most enlightened nations of Europe. Anarchy and confusion have ever been unfavourable to calm philosophic research, whilst they have contributed to bring into view those restless spirits who blaze like a meteor and like a meteor are extinguished, the illuminations of Philosophy are spoken of as the sources of their reveries. But their whole phraseology is equally a perversion of every thing in language and in sentiment. The sacred name of philosophy is profaned in their mouths. No wonder that religion fled from the torch of their philosophy: for their philosophy consists expressly in the confounding the most distinct classes of phenomena and of beings, in assimilating the heavenly animating spark within us to a piece of rude matter, and in degrading man to the level of the brutes, and thus shutting out his fairest prospects. It is not by the ordinary dialectics of the theologian that this sacrilegious confusion can be rectified: this requires an intimate acquaintance with what is characteristic of mind, and what is characteristic of matter, and a comprehensive view of the general laws which regulate the appearances in both classes of objects. Thus, and thus alone, will the divine be able to confute the miserable sophisms of Mirabeau and Diderot and the other *soi-disant* sages of France; and persuade their willing hearers to "render

unto Cæsar the things that are Cæsar's, and to God the things that are God's."

But besides these advances which accrue to different classes of men from this study, there are some effects which are general, and are too important to be passed over unnoticed.

That spirit of dispassionate experimental inquiry which has so greatly promoted this study, will carry with it, into every subject of inquiry, that precision and that constant appeal to fact and experience which characterise it. And we may venture to assert, that the superior good order and method which distinguish some of the later productions in other sciences, have been in a great measure owing to this mathematical spirit, the success of which in natural philosophy has gained it credit, and thus given it an unperceived influence even over those who have not made it their study.

The truths also which the naturalist discovers are such as do not in general affect the passions of men, and have therefore a good chance of meeting with a candid reception. Those whose interest it is to keep men in political or religious ignorance, cannot easily suspect bad consequences from improvements in this science; and if they did, have hardly any pretext for checking its progress. All discoveries accustom the mind to novelty; and it will no longer be startled by any consequences, however contrary to common opinion. Thus the way is paved for a rational and discreet scepticism, and a free inquiry on other subjects. Experiment, not authority, will be considered as the test of truth; and under the guidance of fair experience we need fear no ill as long as the laws of nature remain as they are.

Lastly, since it is the business of philosophy to describe the phenomena of nature, to discover their causes, to trace the connection and subordination of these causes, and thus obtain a view of the whole constitution of nature; it is plain that it affords the surest path for arriving at the knowledge of the great cause of all, of God himself, and for forming proper conceptions of him and of our relations to him: notions infinitely more just than can ever be entertained by the careless spectator of his works. Things which to this man appear solitary and detached, having no other connection with the rest of the universe but the shadowy and fleeting relation of co-existence, will, to the diligent philosopher, declare themselves to be parts of a great and harmonious whole, connected by the general laws of nature, and tending to one grand and beneficent purpose. Such a contemplation is in the highest degree pleasant and cheering, and cannot fail of impressing us with the wish to co-operate in this glorious plan, by acting worthy of the place we hold among the works of God, and with the hopes of one day enjoying all the satisfaction that can arise from conscious worth and consummate knowledge; and this is the worship which God will approve. "This universe (says Boyle) is the magnificent temple of its great Author; and man is ordained, by his powers and qualifications, the high priest of nature, to celebrate divine service in this temple of the universe."

Physiognomics. PHYSIOGNOMICS, among physicians, denote such signs as, being taken from the countenance, serve to indicate the state, disposition, &c. both of the

body and mind: and hence the art of reducing these signs to practice is termed *physiognomy*. Physiognomics.

P H Y S I O G N O M Y,

Various definitions of physiognomy ancient and modern.

IS a word formed from the Greek *συστη nature*, and *γνωσκω I know*. It is the name of a science which occupied much of the attention of ancient philosophers, and which, since the revival of learning, has in a great degree been disregarded. Till of late it has seldom in modern times been mentioned, except in conjunction with the exploded arts of magic, alchemy, and judicial astrology. Within the two last centuries, no doubt, the bounds of human knowledge have been greatly extended by means of the patient pursuit of fact and experiment, instead of the hasty adoption of conjecture and hypothesis. We have certainly discovered many of the ancient systems to be merely creatures of imagination. Perhaps, however, in some instances, we have decided too rapidly, and rejected real knowledge, which we would have found it tedious and troublesome to acquire. Such has been the fate of the science of physiognomy; which certainly merits to be considered in a light very different from alchemy and those other fanciful studies with which it had accidentally been coupled. The work lately published by M. Lavater on the subject has indeed excited attention, and may perhaps tend to replace physiognomy in that rank in the circle of the sciences to which it seems to be intitled.

It does not appear that the ancients extended the compass of physiognomy beyond *man*, or at least animated nature: But the study of that art was revived in the middle ages, when, misled probably by the comprehensiveness of the etymological meaning of the word, or incited by the prevalent taste for the marvellous, those who treated of the subject stretched the range of their speculation far beyond the ancient limits. The extension of the signification of the term was adopted universally by those naturalists who admitted the theory of signatures (see SIGNATURE); and physiognomy came thus to mean, the knowledge of the *internal* properties of any corporeal existence from the *external* appearances. Joannes Baptista Porta, for instance, who was a physiognomist and philosopher of considerable eminence, wrote a treatise on the physiognomy of *plants* (*philognomonica*), in which he employs physiognomy as the generic term. There is a treatise likewise *De Physiognomia Avium*, written we believe by the same person. In the *Magia Physiognomonica* of Gaspar Schottus, *physiognomia humana* is made a *subdivision* of the science.

Boyle too adopts the extensive signification mentioned, which indeed seems to have been at one time the usual acceptation of the word (A). At present physiognomy seems to mean no more than “ a know-

ledge of the moral character and extent of intellectual powers of human beings, from their external appearance and manners.” In the Berlin Transactions for the years 1769 and 1770 there appears a long controversial discussion on the subject of the *definition* of physiognomy between M. Pernetty and M. Le Cat, two modern authors of some note. Pernetty contends, that *all knowledge whatever* is physiognomy; Le Cat confines the subject to the *human face*. Neither seems to have hit the medium of truth. Soon after the celebrated book of Lavater appeared. He indeed defines physiognomy to be, “ the art of discovering the *interior* of *man* by means of his *exterior*; but in different passages of his work he evidently favours the extended signification of Pernetty. This work gave occasion to M. Formey’s attack upon the science itself in the same Berlin Transactions for 1775. Formey strenuously controverts the extent assigned by Lavater to his favourite science.

Before the era of Pythagoras the Greeks had little or no science, and of course could not be scientific physiognomists. Physiognomy, however, was much cultivated in Egypt and India; and from these countries the sage of Samos probably introduced the rudiments of this science, as he did those of many others, generally deemed more important, into Greece. ² Pythagoras probably brought this science to Greece

In the time of Socrates it appears even to have been adopted as a profession. Of this the well-known anecdote of the decision of Zopyrus, on the real character of Socrates himself judging from his countenance, is sufficient evidence. Plato mentions the subject; and by Aristotle it is formally treated of in a book allotted to the purpose. ³ It was a profession brought in the time of Socrates.

It may be worth while to give a brief outline of Aristotle’s sentiments on the subject. ⁴ General outline of Aristotle’s opinions on this subject.

Physiognomy, he in substance observes, had been treated of in three ways: Some philosophers classed animals into genera, and ascribed to each genus a certain mental disposition corresponding to their corporeal appearance. Others made a farther distinction of dividing the genera into species. Among men, for instance, they distinguished the Thracians, the Scythians, the Egyptians, and whatever nations were strikingly different in manners and habits, to whom accordingly they assigned the distinctive physiognomical characteristics. A third set of physiognomists judged of the actions and manners of *the individual*, and presumed that certain manners proceeded from certain dispositions. But the method of treating the subject adopted by Aristotle himself was this; A peculiar form of body is invariably accompanied by a peculiar disposition.

(A) They’ll find it the physiognomics
Of the planets all men’s destinies. HUDIBRAS.

disposition of mind; a human intellect is never found in the corporeal form of a beast. The mind and body reciprocally affect each other: thus in intoxication and mania the mind exhibits the affections of the body; and in fear, joy, &c. the body displays the affections of the mind.

From such facts he argues, that when in man a particular bodily character appears, which by prior experience and observation has been found uniformly accompanied by a certain mental disposition, with which therefore it must have been necessarily connected; we are intitled in all such cases to infer the disposition from the appearance. Our observations, he conceives, may be drawn from other animals as well as from men: for as a lion possesses one bodily form and mental character, a hare another, the corporeal characteristics of the lion, such as strong hair, deep voice, large extremities, discernible in a human creature, denote the strength and courage of that noble animal; while the slender extremities, soft down, and other features of the hare, visible in a man, betray the mental character of that pusillanimous creature.

Upon this principle Aristotle treats of the corporeal features of man, and the correspondent dispositions, so far as observed: he illustrates them by the analogy just mentioned, and in some instances attempts to account for them by physiological reasoning.

At the early period in which Aristotle wrote, his theory, plausible certainly, and even probable, displays his usual penetration and a considerable degree of knowledge. He distinctly notices individual physiognomy, national physiognomy, and comparative physiognomy. The state of knowledge in his time did not admit of a complete elucidation of his general principles; on that account his enumeration of particular observations and precepts is by no means so well founded or so accurate as his method of study. Even his style, concise and energetic, was inimical to the subject; which, to be made clearly comprehensible, must require frequent paraphrases. Aristotle's performance, however, such as it is, has been taken as the ground work and model of every physiognomical treatise that has since appeared.

The imitators of this great man in the 16th and 17th centuries have even copied his language and manner, which are sententious, indiscriminate, and obscure. His comparative physiognomy of men with beasts has been frequently though not universally adopted. Besides his treatise expressly on the subject, many incidental observations on physiognomy will be found interspersed through his other works, particularly in his history of animals.

⁵ Theophrastus's ethic characters form an important branch of physiognomy. Next after Aristotle, his disciple and successor Theophrastus would deserve to be particularly mentioned as a writer on the subject in question. His ethic characters, a singular and entertaining performance, composed at the age of 99, form a distinct treatise on a most important branch of physiognomy *the physiognomy of manners*: but the translations and imitations of La Bruyere are so excellent, that by referring to them we do greater justice than would otherwise be in our power, both to Theophrastus and to our readers. We cannot, however, omit observing, that the accuracy of

observation and liveliness of description displayed in the work of Theophrastus will preserve it high in classical rank, while the science of man and the prominent characteristics of human society continue to be objects of attention.

Polemon of Athens, Adamantius the sophist, and several others, wrote on the subject about the same period. Lately there was published a collection of all the Greek authors on physiognomy: the book is intitled *Physiognomie veteris scriptores Græci. Gr. & Lat. a Franzio Altenb. 1780, 8vo.* From the number of these authors, it appears that the science was much cultivated in Greece; but the professors seem soon to have connected with it something of the marvellous. This we have cause to suspect from the story told by Apion of Apelles: *Imaginem adeo similitudinis indiscretæ pinxit, ut (incredibile dictu) Apion Grammaticus Scriptum reliquerit quemdam ex facie hominum addicentem (quos melaepiskopos vocant) ex iis dixisse aut futuræ mortis annos, aut præteritæ.* The novitiates of the Pythagorean school were subjected to the physiognomical observation of their teachers, and it is probable the first physiognomists by profession among the Greeks were of this sect. They, too, to whom, from the nature of their doctrines and discipline, mystery was familiar, were the first, it is likely, who exposed the science of physiognomy in Greece to disgrace, by blending with it the art of divination.

From the period of which we have been treating to the close of the Roman republic, nothing worthy of remark occurs in the literary history of physiognomy. About the last mentioned era, however, and from thence to the decline of the empire under the later emperors, the science appears to have been cultivated as an important branch of erudition, and assumed as a profession by persons who had acquired a superior knowledge in it.

In the works of Hippocrates and Galen, many physiognomical observations occur. Cicero appears to have been peculiarly attached to the science. In his oration against Piso, and in that in favour of Roscius, the reader will at the same time perceive in what manner the orator employs physiognomy to his purposes, and find a curious instance of the *ancient* manner of oratorical *abuse*.

Many physiognomical remarks are to be found likewise in the writings of Sallust, Suetonius, Seneca, Pliny, Aulus, Gellius, Petronius, Plutarch, and others.

That in the Roman empire the science was practised as a profession, ample evidence appears in the writings of several of the authors just mentioned. Suetonius, for instance, in his *Life of Titus*, mentions that Narcissus employed a *physiognomist* to examine the features of Britannicus, who predicted that Britannicus would not succeed, but that the empire would devolve on Titus.

The science of physiognomy shared the same fate with all others, when the Roman empire was overthrown by the northern barbarians. About the beginning of the sixteenth century it began again to be noticed.—From that time till the close of the seventeenth, it was one of the most fashionable studies. Within that space have appeared almost all the improved modern authors on the subject (B)

⁶ Other Greek authors on this subject.

⁷ The science was then coupled with something of the marvellous.

It has been unfortunate for physiognomy, that by many of these writers it was held to be connected with doctrines of which the philosophy of the present day would be ashamed. With these doctrines it had almost sunk into oblivion.

10
Particular
studies have
peculiarly
prevailed at
particular
times.

In every period of the history of literature there may easily be marked a prevalence of particular studies. In the early period, for instance, of Grecian literature, *mythological morality* claimed the chief attention of the philosophers. In the more advanced state of learning in Greece and in Rome, *poetry, history, and oratory*, held the pre-eminence. Under the latter emperors, and for some time afterwards, the history of *theological controversies* occupied the greatest part of the works of the learned. Next succeeded *metaphysics*, and *metaphysical theology*. These gave place to *alchemy, magic, judicial astrology*, the doctrine of signatures and sympathies, the *mystic, theosophic, and Rosicrucian theology*, with physiognomy. Such were the pursuits contemporary with the science which is the object of our present inquiry. It is no matter of surprise, that, so associated, it should have fallen into contempt. It is not unusual for mankind hastily to reject valuable opinions, when accidentally or artificially connected with others which are absurd and untenable. Of the truth of this remark, the history of theology, and the present tone of theological opinions in Europe, furnish a pregnant example.

To physiognomy, and the exploded sciences last mentioned, succeeded *chymical philosophy*; which gave place to *modern poetry and natural philosophy*; to which recently have been added the studies of *rational theology, chemistry, the philosophy of history, the history of man, and the science of politics*.

11
The observations
of the writers
of the present
century on this
subject.

About the commencement of the eighteenth century, and thence forward, the occult sciences, as they are termed, had declined very considerably in the estimation of the learned; and those who treated of physiognomy forbore to disgrace it by a connection with those branches of ideal learning with which formerly it had been invariably conjoined. In Britain, Dr Gwither noticed it with approbation.—His remarks are published in the Philosophical Transactions, vol. xviii.; and Dr Parsons chose it for the subject of the Croonian lectures, published at first in the second supplement to the 44th volume of the Philosophical Transactions, and afterwards (1747) in a separate treatise, entitled *Human Physiognomy explained*.

The observations, however, of these writers, as well as of Lancilius, Haller, and Buffon, relate rather to the transient expression of the passions than to the permanent features of the face and body. The well-known characters of Le Brun likewise are illustrative of the transient physiognomy, or (as it is termed) pathognomy.—See *PASSIONS in Painting*.

12
We find
nothing
very im-
portant
till the
controversy
between
Pernetty
and Le Cat.

During the present century, although physiognomy has been now and then attended to, nothing of importance appeared on the subject till the discussion already

mentioned between Pernetty and Le Cat, in the Berlin Transactions. The sentiments of these authors, in so far as relates to the *definition* of physiognomy, have been above noticed. Their essays are besides employed in discussing the following questions: 1st, Whether it would or would not be advantageous to society, were the character, disposition, and abilities, of each individual so marked in his appearance as to be discovered with certainty?

2^{dly}, Whether, on the supposition that by the highest possible proficiency in physiognomy, we could attain a knowledge in part only of the internal character, it would be advantageous to society to cultivate the study, mankind being in general imperfect physiognomists?

No reasoning *a priori* can possibly determine these questions. Time and experience alone must ascertain the degree of influence which any particular acquisition of knowledge would have on the manners and characters of mankind; but it is difficult to conceive how the *result* of any portion of knowledge, formerly unknown, and which mankind would be *permitted* to discover, could be any thing but beneficial.

Soon after this controversy in the Berlin Transactions, appeared the great work of M. Lavater, dean of Zurich, which has excited no inconsiderable portion of attention in the literary world. The work itself is magnificent: that circumstance, as well as the nature of the subject, which was supposed to be fanciful, have contributed to extend its fame; and certainly, if we may judge, the book, though many faults may be detected in it, is the most important of any that has appeared on the subject since the days of Aristotle. Lavater professes not to give a complete synthetical treatise on physiognomy, but, aware that the science is yet in its infancy, he exhibits fragments only illustrative of its different parts. His performance is no doubt desultory and unconnected. It contains, however, many particulars much superior to any thing that had ever before appeared on the subject.

With the scholastic and systematic method adopted by the physiognomists of the last and preceding centuries, Lavater has rejected their manner of writing, which was dry, concise, indeterminate, and general: his remarks, on the contrary, are for the most part precise and particular, frequently founded on distinctions extremely acute. He has omitted entirely (as was to be expected from a writer of the present day) the astrological reveries, and such like, which deform the writings of former physiognomists; and he has with much propriety deduced his physiognomical observations but seldom from anatomical or physiological reasoning. Such reasoning may perhaps at some future period become important; but at present our knowledge of facts, although extensive, is not so universal as to become the stable foundation of particular deductions. Lavater has illustrated his remarks by engravings; a method first adopted by Baptista Porta.—

Lavater's

13
Lavater's
celebrated
work.

Michael Schottus, Gaspar Schottus, Cardan, Tañnerus, Fludd, Behmen, Barclay, Claromontius, Conringius, the commentaries of Augustin Niphus, and Camillus Balbus on the Physiognomica of Aristotle,—Spontanus, Andreas Henricus, Joannes Digander, Rud. Groelenius, Alex. Achilinus, Joh. Prætorius, Jo. Belot, Guliel. Gratalorus, &c. They are noticed in the Polyhistor. of Morhoff. vol. i. lib. 1. cap. 15. § 4. and vol. ii. lib. 3. cap. 1. § 4.

Lavater's engravings are very numerous, often expressive, and tolerably executed.

The opinions of this celebrated physiognomist are evidently the result of actual observation. He appears indeed to have made the science his peculiar study, and the grand pursuit of his life. His performance exhibits an extended comprehension of the subject, by a particular attention to *offset* physiognomy, and the effect of *profiles* and *contours*. His style in general is forcible and lively, although somewhat declamatory and digressive. His expressions are frequently precise, and strikingly characteristic; and the spirit of piety and benevolence which pervade the whole performance render it highly interesting.

The defects of the work, however, detract much from the weight which Lavater's opinions might otherwise challenge. His imagination has frequently so far outstript his judgment, that an ordinary reader would often be apt to reject the whole system as the extravagant reverie of an ingenious theorist. He has clothed his favourite science in that affected mysterious air of importance which was so usual with his predecessors, and describes the whole material world to be objects of the universal dominion of physiognomy*. He whimsically conceives it necessary for a physiognomist to be a well-shiped handsome man †. He employs a language which is often much too peremptory and decisive, disproportioned to the real substance of his remarks, or to the occasion of making them. The remarks themselves are frequently opposite in appearance to common observation, and yet unsupported by any illustrations of his.

Lavater certainly errs in bestowing too great a reliance on single features, as the foundation of decision on character. His opinions on the physiognomy of the ears, hands, nails, and feet, of the human species, on hand-writing, on the physiognomy of birds, insects, reptiles, and fishes, are obviously premature, as hitherto no sufficient number of accurate observations have been made, in regard to either of these particulars, to authorize any conclusion. He has erred in the opposite extreme, when treating of the important topic of national physiognomy, where he has by no means professed the subject so far as facts might have warranted. We must farther take the liberty to object to the frequent introduction of the author's own physiognomy throughout the course of his work. His singular remarks on his own face do not serve to prejudice the reader in favour of his judgment, however much his character may justify the truth of them. We must regret likewise, for the credit of the science, that the author's singularly fanciful theory of apparitions should so nearly resemble a revival of the antiquated opinions of the sympathists.

To these blemishes, which we have reluctantly enumerated, perhaps may be added that high impassioned tone of enthusiasm in favour of his science everywhere displayed throughout the work of this author, which is certainly very opposite to the cool patient investigation besitting philosophy. To that enthusiasm, however, it is probable that in this instance (as is, indeed, no unfrequent effect of enthusiasm) we are indebted for the excellency which the author has attained in his pursuit; and it possesses the salutary tendency of put-

ting us on our guard against a too implicit acquiescence in his physiognomical decisions.

In the Berlin Transactions for 1775, there appears a formal attack upon Lavater's work by M. Formey. This essay we have already mentioned. After disputing the propriety of the extensive signification applied by Lavater and Pernetty to the term physiognomy, M. Formey adopts nearly the same definition which we conceive to be the most proper, and which we have put down as such near the beginning of this article. He allows that the mental character is intimately connected with, and sensibly influenced by, every fibre of the body; but his principal argument against physiognomy is, that the human frame is liable to innumerable accidents, by which it may be changed in its external appearance, without any correspondent change of the disposition; so that it surpasses the extent of the skill of mortals to distinguish the modifications of feature that are natural from those which may be accidental. Although, therefore, the science of physiognomy may be founded in truth, he infers that the Deity only can exercise it.

M. Formey further contends, that education, diet, climate, and sudden emotions, may even the temperaments of ancestors, affect the cast of human features; so that the influence of mental character on these features may be so involved with, or hidden by, accidental circumstances, that the study of physiognomy must ever be attended by hopeless uncertainty. These objections are worthy of notice, but they are by no means conclusive.

We shall give a specimen of M. Lavater's manner of treating the subject on the opposite side of the question: a specimen, not in Lavater's precise words, but conveying more shortly an idea at once of his sentiments, and of his manner of expressing them.

No study, says he, excepting mathematics, more justly deserves to be termed a *science* than physiognomy. It is a department of physics, including theology and belles letters, and in the same manner with these sciences may be reduced to rule. It may acquire a fixed and appropriate character; it may be communicated and taught.

Truth or knowledge, explained by fixed principles, become science. Words, lines, rules, definitions, are the medium of communication. The question, then, with respect to physiognomy, will thus be fairly stated. Can the striking and marked differences which are visible between one human face, one human form, and another, be explained, not by obscure and confused conceptions, but by certain characters, signs, and expressions? Are these signs capable of communicating the vigour or imbecility, the sickness or health, of the body; the wisdom, the folly, the magnanimity, the meanness, the virtue, or the vice, of the mind?

It is only to a certain extent that even the experimental philosopher can pursue his researches. The active and vigorous mind, employed in such studies, will often form conceptions which he shall be incapable of expressing in words, so as to communicate his ideas to the feebler mind, which was itself unable to make the discovery: but the lofty, the exalted mind, which soars beyond all written rule, which possesses feelings and

and energies reducible to no law, must be pronounced unscientific.

21
Phyfiog-
nomical
truth may
be defined
and com-
municated
to a certain
length.

It will be admitted, then, that to a certain degree phyfiogonomical truth may as a science be defined and communicated. Of the truth of the science there cannot exist a doubt. Every countenance, every form, every created existence, is individually distinct, as well as different, in respect of class, race, and kind. No one being in nature is precisely similar to another. This proposition, in so far as regards man, is the foundation-stone of phyfiogonomy. There may exist an intimate analogy, a striking similarity, between two men, who yet being brought together, and accurately compared, will appear to be remarkably different. No two minds perfectly resemble each other. Now, is it possible to doubt that there must be a certain native analogy between the external varieties of countenance and form and the internal varieties of the mind? By anger the muscles are rendered protuberant: Are not, then, the angry mind, and the protuberant muscles, as cause and effect? The man of acute wit has frequently a quick and lively eye. Is it possible to resist the conclusion, that between such a mind and such a countenance there is a determinate relation?

Every thing in nature is estimated by its phyfiogonomy; that is, its external appearance. The trader judges by the colour, the fineness, the exterior, the *phyfiogonomy* of every article of traffic; and he at once decides that the buyer "has an honest look," or "a pleasing or forbidding countenance."

22
This
know-
ledge,
however
improved,
would not
be detri-
mental
to man.

That knowledge and science are detrimental to man, that a state of rudeness and ignorance are preferable and productive of more happiness, are tenets now deservedly exploded. They do not merit serious opposition. The extension and increase of knowledge, then, is an object of importance to man: and what object can be so important as the knowledge of man himself? If knowledge can influence his happiness, the knowledge of himself must influence it the most. This useful knowledge is the peculiar province of the science of phyfiogonomy. To conceive a just idea of the advantages of phyfiogonomy, let us for a moment suppose that all phyfiogonomical knowledge were totally forgotten among men; what confusion, what uncertainty, what numberless mistakes, would be the consequence? Men destined to live in society must hold mutual intercourse. The knowledge of Man imparts to this intercourse its spirit, its pleasures, its advantages.

23
It affords
greatmen-
tal gratifi-
cation.

Phyfiogonomy is a source of pure and exalted mental gratification. It affords a new view of the perfection of Deity; it displays a new scene of harmony and beauty in his works; it reveals internal motives, which without it would only have been discovered in the world to come. The phyfiogonomist distinguishes accurately the permanent from the habitual, the habitual from the accidental, in character. Difficulties, no doubt, attend the study of this science. The most minute shades, scarcely discernible to the unexperienced eye, denote often total opposition of character. A small inflexion diminution, lengthening or sharpening, even though but of a hair's breadth, may alter in an astonishing degree the expression of countenance and character. How difficult then, how impossible indeed, must this variety of the same countenance render precision? The seat of character is often so hidden, so mask-

24
Difficul-
ties in the
study.

ed, that it can only be detected in certain, perhaps uncommon, positions of countenance. These positions may be so quickly changed, the signs may so instantaneously disappear, and their impression on the mind of the observer may be so slight, or these distinguishing traits themselves so difficult to seize, that it shall be impossible to paint them or describe them in language. Innumerable great and small accidents, whether physical or moral, various incidents and passions, the diversity of dress, of position, of light or shade, tend to display the countenance often in so disadvantageous a point of view, that the phyfiogonomist is betrayed into an erroneous judgment of the true qualities of the countenance and character. Such causes often occasion him to overlook the essential traits of character, and to form a decision on what is purely accidental.—How surprisingly, for instance, may the smallpox disfigure the countenance, and destroy or confound, or render imperceptible, traits otherwise the most decisive?

25
We shall, then, continues Lavater, grant to the May one
opposer of phyfiogonomy all he can ask; and yet we do day be ob-
not live without hopes that many of the difficulties viated.
shall be resolved which at first appeared inexplicable.

26
He then proceeds to a specific illustration of his The na-
subject under a great variety of titles, in which he ture of
treats of human nature in general, and of each parti- Lavater's
cular feature separately. work.

To enumerate the different divisions of his book would not be more satisfactory to our readers than the perusal of the *contents* of the book itself; and an attempt to epitomize even the essential substance of the vast multiplicity of matter contained in his essays, (which are yet only *fragments*, and to which indeed he himself does not pretend to give any higher appellation), would extend this article to a disproportionate length. Such an abridgement, after all, would convey no solid information on a subject which merits all the time and study that an attentive perusal of Lavater's works at large would require.

27
From the historical deduction of the literary progress Probable
of phyfiogonomy which we have thus attempted to lay causes of
before our readers, it appears, that although the the disfre-
science has fallen into disrepute, there can scarcely be pute into
mentioned a period in which any cultivation of science which this
took place when phyfiogonomy was not likewise the science has
study, nay sometimes even the profession, of men of fallen.

The reasons why at present so little attention is paid to the subject probably are,

1st, That it has been treated in conjunction with subjects now with propriety exploded: And,

2^{dly}, That it has been injured by the injudicious assertions and arguments of those who have undertaken its defence.

Sometimes, however, the wise and the learned may err. The use of any thing must not be rejected for no better reason than that it is capable of abuse. Perhaps the era is not distant when phyfiogonomy shall be reinstated in the rank which she merits among the valuable branches of human knowledge, and be studied with that degree of attention and perseverance which a subject deserves so essentially connected with the science of man.

That there is an intimate relation between the dif-
positions

28 There is a relation between the dispositions of the mind and the features of the face. positions of the mind and the features of the countenance is a fact which cannot be questioned. He who is sinking under a load of grief for the death of an affectionate wife or a dutiful child, has a very different cast of features from the man who is happy in the prospect of meeting his mistress. A person boiling with anger has a threatening air in his countenance, which the most heedless observer never mistakes; and if any particular disposition be indulged till it become habi-

tual, there cannot be a doubt but that the corresponding traces will be so fixed in the face as to be discernible by the skilful physiognomist, under every effort made to disguise them. But when we attempt to decide on a man's intellectual powers by the look of his face, we are often deceived; and in these cases we have reason to believe that Lavater himself has fallen into the grossest mistakes.

PHYSIOLOGY,

1 Definition. IS a Greek word, which, in strict etymology, signifies that which discourses of nature: but in its common use, it is restricted to that branch of physical science, which treats of the different functions and properties of living bodies; while by living bodies are meant those which are by a certain organized structure enabled to grow and propagate their kind.

By this definition, physiology must necessarily have for its object the explanation of that internal organical economy in plants and animals, which nature has devised for the preservation of the individual, and for the continuance and propagation of the species.

2 Division. It is naturally divided into two kinds, particular and general. The former treats of the properties and functions of the individual or species, as may be seen in the article ANATOMY; the latter is the subject of our present discussion, and treats of those functions and properties which are general or common to all living bodies.

3 Utility of physiology. To the genuine naturalist no subject presents such a field of amusement and instruction. When as complete as the state of contemporary science will admit, it will exhibit a general result of all those experiments and observations that have purposely been made or occasionally contributed to illustrate the phenomena of animated matter; and when it shall reach that summit of perfection to which the efforts of genius may carry it, it may be enabled to diffuse a light, of which the naturalist of the present day can have no just or adequate conception: Particularly in physics, anatomy, botany, and in natural history, its happy effects may be numerous and great. On many occasions it may there introduce order for confusion, certainty for doubt; and may be expected to enthroned science in various places which are now occupied by fancy and conjecture.

4 Its near approach to metaphysics, and the difference pointed out. Of all the branches of physical science it certainly makes the nearest approach to the region of metaphysics; but yet there is a difference between these, though it may not be very easy to point out the precise line of termination. Physiology, as already defined, being that science which has for its object the organical economy of living bodies, the word organical, we think, here should mark the distinction.

Wherever the economy of living bodies indicates design, and cannot result from any combination or structure of organs, it must be supposed the effect of something different from matter, and whose explanation belongs to that which is called metaphysics, or which we might term the philosophy of mind. By ascribing indeed to the glandular contents within the cranium and to

that fiction animal spirits, the motive of action, the superficial and ill informed may have been led to an opinion that perception, memory, and imagination, are the functions of the cerebrum, the medulla oblongata, and cerebellum; that the soul is a consequence of organization; and the science which treats of it only a particular branch of physiology. But mind and its faculties are now so well understood and investigated, that this opinion can seldom prevail but where penetration is not remarkable for its acuteness, or where reflection, reading, and research, have long been confined within the limits of a narrow circle.

Instead of mind being the effect of organization, we readily allow that every living system of organs supports mind, and that in the study of such systems the physiologist must often meet with many phenomena that are less singular than simple perception, and yet for which he cannot account by any knowledge which he possesses of organic powers. This truth we partly acknowledge, when, like ancient Athens erecting her altars to unknown gods, we retreat to those asylums of ignorance, the vis insita, the vis nerva, the vis vitalis, the vis medicatrix, and a number of others of the same kind.

5 We choose here to mark precisely the bounds of physiology, because we have always been led to imagine that it would be extremely fortunate for science that all its divisions were accurately defined, that each were restricted to its own sphere, where alone it is useful and were never allowed to make encroachments on the province of another, where its only tendency can be to mislead and subvert all ideas of arrangement.

In its progress of improvement, physiology has been much and often retarded from a want of attention to this circumstance. The time has been when its place was occupied almost entirely by an absurd and ridiculous philosophy, which accounted for every thing by an hypothesis, and which pretended to cure wounds a hundred miles distant by a power of sympathy.

6 Nay, as if its nature were not yet ascertained, in some books whose titles promise much information on the functions of organs, we meet with only a pleasing account of design and intelligence, and a few lessons, when the fancy is warm, how to exclaim and how we should wonder; or, after similar professions in the titles of others, we are presented with only a curious display of the art of logic. To a fact or two we see numerous chains of reasoning appended. On these chains are hanging important and general conclusions; and these conclusions afterwards uniting, suspend an elaborate

Preliminary observations.

7
Anal of mathematics

borate system of pathology. The whole has a wonderfully specious appearance; but upon applying the touchstone of experiment, the system falls, the conclusions turn out to be false, the chains are found connected with the fact by only a conjecture or some popular opinion of the time; most of their links are creations of fancy, and their joinings such logical associations as have no analogy or prototype in nature.

Instead of logic, however, a pompous parade of mathematical learning has been *sometimes* introduced. This has always an imposing aspect, and its presence here may require to be examined with some care. It must be allowed, that it would have indeed been rather surprising if logic and metaphysics had been employed, and mathematics carrying science in their name had not been thought of. Their character had always been deservedly high; and there was scarcely a department of knowledge to which they had not in some respect contributed their aid: their researches, too, had not been confined to mere number and quantity alone; they had explained the momentum of bodies, and all those motions which arise from percussion and gravitation; they had ascertained the distance of the stars the velocity, magnitude, and orbits of the planets; they had accounted for the phases of the moon, the phenomena of eclipses, and return of comets; and bringing their knowledge from the heavens to the earth, they had shown the causes of the days and nights, of the years and the seasons, in all their varieties throughout the globe: they had taught the chronologer how to dispose of the periods of time, and how he might best assist the historian to arrange his events: they had pointed out the origin of tides; had informed the mariner how to direct his course through the ocean; and had taught the geographer how to describe the regions of the earth, and assist the traveller in his laudable pursuits after knowledge and science: they, in short, had unfolded the wonders of mechanism; and, diffusing light over every branch of that philosophy which is called *mechanical*, and has long been dignified with the name of *natural*, had afforded the finest specimens of reasoning with which the human mind is acquainted.

8
Introduced by Bellini.

A science of such distinguished utility could hardly fail to excite the admiration of all who knew it, or even had heard of it. And at a period when it was fashionable, it was scarcely possible for the physiologist to pass it unnoticed: the truth is, he very soon discovered its excellency. Bellini of Florence first introduced it; and it was at last so warped with physiology, that there were some who could hardly conceive a physiology existing without it. The justly celebrated Professor Borelli, one of its most enthusiastic admirers, employed it so well in showing how the muscles acted as ropes and the bones as levers, that he thence explained with the happiest effect the phenomena of standing, of walking, of leaping, of flying, and of swimming, in different animals: this task he performed in the first part of his famous work *De Motu Animalium*. But, wishing to know more of the animal economy, and feeling himself inspired with new hopes, he ventured in the second to explain also in the same way the interior motions and their proximate causes on the principles of mechanism: he there gives a minute account of the motion of the muscles, of the heart and its pulsation, of the circulating blood, of the office of the lungs, the kid-

9
Extended by Borelli.

neys, and the liver, of the nervous fluid and the seminal secretion; of vegetation, generation, nutrition, of hunger and thirst, of pain, of lassitude, and the heat of fever.

Preliminary observations.

Mathematics by him were considered as almost universal interpreters; for except the mechanical he seemed to acknowledge no other secondary powers in nature. He thought, with Plato, that God himself was always geometrizing; and was fully persuaded that physical knowledge could not be acquired but through the medium of geometrical demonstrations and forms. These opinions had begun to be general, when his learned work was published at Rome in the year 1676; and they were no unequivocal symptoms that the reigning philosophy of that time was now in the last stage of decay.

Still, however, as the spirit of that philosophy was not wholly extinguished, physiology continued to be much infested with its metaphysical and logical disputes, and with its physical doctrines of forms of particular ferments, its antipathies, sympathies, its occult qualities, and subtle atoms.

For these reasons, in his inaugural dissertation at Leyden, delivered in the year 1692, the learned Pitcairn expresses a wish that medicine were made a distinct science; that it were established on mechanical principles, on fewer postulates, and more data; and that it was supported by a clear train of mathematical reasoning, which would defy the attacks of the sophist, and which would not be liable to the fluctuations of opinion and prejudice. These sentiments were warmly supported by the great Boerhaave, who, in his aphorisms, has founded his reasonings on the structure of the parts and the laws of mechanics, and to whom an edition of Borelli was dedicated in 1710.

TO
By Pitcairn, and others.

Pitcairn, however, was not content with barely expressing his wishes. Seeing with regret that the state of medicine could never be improved as long as it was connected with the philosophy which was then in fashion, he seemed anxious to effect a separation; and for such a step he wished to have only some plausible pretext. This pretext *was not long wanting*; and was, to be sure, one of the most whimsical that could have well presented itself to his fancy. It occurred to him that the study of medicine was prior to philosophy; that it had begun its course with astronomy, at the time when diseases were supposed the consequence of offended Deity; that all along, as it had shared the fate of astronomy, and had equally suffered in the common disgrace of judicial astrology, it was highly reasonable, in his opinion, that it should still follow the fate of its friend; that it should be established on similar principles, and should be demonstrated by that reasoning which might experience the shock of ages without being moved. So attached was he to the geometrical mode of demonstration, that in his dissertations he appeared to consider it as indeed the only species of evidence, excepting the senses, that could be relied on. But here he was certainly venturing too far; so rash an opinion, and on which had he previously consulted with prudence, might have been suppressed, was fatal to his cause. We must here therefore date the commencement of those attacks to which his system was afterwards exposed. Such an indiscreet species of pedantry was but ill calculated to procure a generally favourable reception for a book with so extraordinary a title as the *Physico-mathematica*.

II
Abused.

Preliminary observations. *mathematical Elements of Medicine.* Many learned and ingenious men, the greater part of whose knowledge had depended chiefly on the evidence of testimony, were now disposed to examine, with a steady and awakened eye, his boasted demonstrations. The consequence was that which might have been expected: the result of their inquiries was wholly inauspicious to those new applications of geometry: they found that his facts and experiments were few, that his postulates were endless, and that no mathematical reasoning whatever could extract truth from a false hypothesis, or could fairly deduce a general conclusion from particular premises. The Doctor, they observed, had imposed upon himself, in imagining that either certainty or truth was naturally inherent in any mere geometrical forms; these forms, they said, had been often abused: Plato had thought them somewhat divine; the superstitious had employed them as charms; Pythagoras had made them the symbols of his creed; and even in the writings of the learned professor himself they frequently served no other purpose but to give an air of importance to trifles; to bestow on error the appearance of science; and to give a simple and a trite remark the look of research, and of acute and profound erudition.

12 Rejected. It is unnecessary to recal here the satirical wit, or more properly the scurrilous abuse, with which this system and its author were treated. The mechanic physiology has now sunk into such contempt, that the most illiterate affect to smile at the mention of its name; they seem to forget, or, what is more probable they never knew, that it once was honoured with the great names of Borelli, Boerhaave, and Newton; and their reading perhaps cannot inform them that it was a noble step to improvement; that it explained the structure of the eye, the movement of the bone, and force of the muscle, and that it may yet perhaps be the means of many interesting discoveries in the living body: discoveries, however, which Heaven will reserve for other minds than those which it makes merely to receive the impressions of the day.

13 Perhaps too rashly. A frequent mistake into which the mechanical philosophers had fallen, was their hopes of being able to account for digestion by the muscular force and action of the stomach. The more they reasoned from this supposition, the more widely they wandered from the truth. A thought of Vallisneri, that in acting mechanically, the stomach was as liable to be affected as its contents, gave a hint to Reaumur. On this hint he began immediately a set of experiments; and from a number that were clear and decisive, concluded that digestion was performed by a solvent. Here was a fair introduction to chemistry; the action of solvents was never yet satisfactorily explained by mechanic powers. A new era therefore commences; and chemistry now, in physiological investigations, holds that place which was formerly possessed by geometry and mechanics.

14 Introduction of chemistry. Nor is chemistry undeserving of this rank. From a small beginning, and from modestly professing to observe merely the different phenomena which are the effects of heat and of mixture, it has risen like astronomy to the first eminence among the sciences. By its numerous researches it has found widely diffused over nature a variety of singularly active bodies, which are called *salts*. Of these salts it has noticed some which

change a blue vegetable tincture into green, and others which change that tincture into red: the former of these it has called *alkalis*, and the latter are known by the name of *acids*. It has observed, that when acids, and alkalis are brought into contact, and either of them nearly in a fluid state, they encounter with violence, effervescence and heat, and form a salt, which being neither acid nor alkaline, is called *neutral*. It has been remarked that all these salts, whether volatile or fixed, whether fluid or concrete, have each permanently uniform characters; and that, though sometimes blended in a mixture, or made to evaporate in a solution, yet when they are separated they resume their taste, their smell, their colour, and their form, and exhibit, as before, the same power in dissolving earths, metals, and stones, and in making inflammable bodies to smoke, to kindle and explode with a loud noise. All, however, act not alike upon all bodies; those acids which dissolve iron remain quite harmless upon gold. And chemistry here has been led to observe that particular salts show a preference for particular bodies, that there is in them an appearance of choice, and that their character is never to be known but by studying their different elective attractions.

Besides salts, chemistry of late has also discovered a number of bodies that are still more wonderful, still more active, and some of them at least still more widely diffused over nature. These are certain aeriform fluids which are called *gases*: these gases, like the mind itself are discernible only by their effects; all are elastic, and all are combined with the principle of heat. Their kinds are various; some are inflammable, some are saline and soluble in water, some are neither the one nor the other, and some distinguished by the name of *airs*, maintaining combustion and respiration: their importance is such that there is not a single process in chemistry, nor perhaps one regular process in nature, "in which the phenomena of the disengagement or fixation of heat and the disengagement or fixation of elastic fluids, are not observed either separately or together." Two of these fluids compose water, two the nitric acid, two ammonia, and three of them are found in atmospheric air; one of them is thought, with a good deal of reason, to be the alkaligenous principle in bodies, and two of them to be the constituents of oil: the principle of acidity is already known to be one of the two which compose water. The same fluid oxidates metals, supports flame during combustion, communicates heat to the circulating blood, and maintains life in the act of respiration.

By that knowledge which it thus has acquired of salts and of gases, by its more ingenious modes of analysis, and by some discoveries which it has made concerning the nature of heat and of light, chemistry is now able to account for many phenomena that before were inexplicable. In France particularly it has been recently extending its researches with a good deal of ardour towards the phenomena of both the animal and vegetable kingdoms: it has there found its salt and its gases, its heat, and its light, active and busy.

It is more than a century since it observed that plants were nourished by pure water and atmospheric air; that from these alone they derived their extracts, their mucilage, their oil, their coal, their acids, their alkalis, and aroma. But since the discovery of different kinds

Preliminary observations.

17 Gases.

18

The food of plants.

Preliminary observations

of elastic fluids, it has further remarked that they grow rapidly in hydrogenous gas (A), and in air mixed with carbonic acid; that assailed by light their leaves absorb hydrogen from water, carbone from the acid of which they are so fond; and thus decomposing the one and the other, disengage from both the oxygenous principle or vital air, and restore to the atmosphere salubrity and health.

19
Animal powers.

Leaving vegetables, which, by analysis in close vessels and in red hot pipes, it has reduced to hydrogen, oxygen, azote, and charcoal, it has made discoveries no less important in the animal kingdom. It has found that the food of the nobler animals, which immediately or remotely is prepared by vegetables, is generally acted upon by a solvent: it has proved by experiment that the animal organs can fix azote; can decompose atmospheric air; can form lime, iron, and carbonic acid, as well as vegetables, produce a number of saline substances, which no art could detect in their food. Nor is it here that such discoveries are meant to terminate; these seemingly creative powers of vegetation and of animalization, with other phenomena in the structure and economy of living bodies, chemistry imagines that it will yet be able to explain. We may safely venture, however, to predict that something more than its present knowledge of the various effects of heat and of mixture will in this case be found necessary to ensure success. The late discovery of elastic fluids and their singular properties afford the strongest reasons to suspect that we yet may be ignorant of many agents which nature employs in the functions of bodies. But whatever be the truth, we are almost certain that these agents discovered by the chemists are not alone concerned. Electricity, magnetism, and what have been called animal electricity and animal magnetism, must not be excluded from acting some part. The growth of plants, it is well known, is considerably affected by the electrical state of the atmosphere; it is sensibly promoted by a proper use of the vegetable electric meter, and has been said to indicate a difference between the negative and positive electricities, whether these be kinds or states of the fluid. Such too is our present knowledge that electricity as yet seems the only cause to which we can ascribe the seeming chemical affinities of the dew; its constant practice in avoiding some bodies its predilection for others, and particularly its attachment to the living points of plants and of leaves; nor is this electricity wholly unconnected with the animal kingdom; when we think of its singular fondness for points, it occurs that one intention of our hairs may probably have been to collect and diffuse it. It is plainly excited in cross rubbing the hair of some animals, and when we wear silk, it is frequently accumulated upon the surface of our own bodies.

21
Animal electricity.

The iron found in plants and in animals is certainly somewhat of a striking circumstance, and cannot be denied to be one reason why magnetism should not be wholly overlooked.

As for animal electricity, or what has been called *se*, it is now, we believe, generally allowed to hold an important place in the system. It is very perceptible

in all those nerves which are subservient to voluntary motions; nor is it limited to these alone. In several instances where metals were applied to the nerves of the heart, which nature has destined to spontaneous motions, they were seen to awaken the dormant powers in the muscular fibres of that viscus. We here speak only of the nerves; but the *Torpedo*, the *Gymnotus electricus*, and *Silurus electricus*, possess a particular structure of organs for collecting this fluid, for discharging it at pleasure, and for giving a shock. If those who are accustomed to the common kind of electrical experiments, may at first be surprised that this electrical fluid in the animal is not discharged from the nerves by water, or any other metallic conductor that is pure and unmixed, another fact, which is fully as striking, though it has not been hitherto mentioned by any observer known to us, appears to merit equal attention: Cut away the leg of a frog, uncover a part of the crural nerve, place the limb now on a table on which an electrifying machine is working, you will see the muscles strongly convulsed at every spark which you draw from the conductor, but remaining motionless upon the discharge of the Leyden phial.

Preliminary observations

Animal electricity naturally suggests animal magnetism. This last has been productive of more wonders in the human frame than all the preceding agents together. Under the management of Mesmer at Paris, and his pupil Deslon, it filled all who observed its effects with surprise and astonishment. It seemed to unshackle the powers of the mind, and affect the whole animal economy; it excited the most extraordinary emotions; it roused and allayed the different passions; it changed aversion into love, and love into aversion; it created pain, it healed wounds, and cured diseases as if by enchantment.

22
And animal magnetism.

These discoveries were made by a quack, who knew not the cause by which he produced so singular appearances. The celebrated Franklin, who first supposed that the electrical fluid was the lightning, was placed at the head of those gentlemen who declared that this species of magnetism was the same power that had long been known under the name of *imagination*.

This last discovery, if the blushing pride of modern philosophy could but stoop to improve an important hint, though originally suggested and by empiric, might greatly enlarge our knowledge of mind, and explain some things in the animal economy which appear yet to require a solution. At any rate, it sufficiently proves that the influence of mind is very extensive in the higher parts of animal creation. Many facts would argue that it increases as we rise in the scale: but the sole intention here was to show, that chemical agents are neither almighty nor every where present; that in the internal organical economy of living bodies they act but a part; and that, like the other agents in nature, they are obliged to confine their operations within those limits which the great Author of being has prescribed.

The aid which anatomy affords to physiology is now to be considered. Physiology in general and the study

23
The use of anatomy in physiology.

(A) Hydrogenous gas acts with more energy than any other substance in dissolving carbone; it mixes with carbonic acid and with azote, and sometimes holds in solution sulphur and phosphorus. See Fourcroy's *Discourse on modern chemistry*.

Preliminary observations.

study of anatomy are so closely connected, that, as Haller imagined, they can hardly be separated even in idea. In his opinion, the man who should attempt to become a physiologist without anatomy, would act as wisely as the mathematician who, without seeing the wheels or the pinions, or without knowing the size, the proportions, or the materials of any machine, would yet presume from mere calculation to determine its powers, its properties, and uses. In this comparison, the importance of anatomy, we are really persuaded, is not represented in a light too strong; nor does that medium through which it has been viewed appear to have magnified beyond nature.

24 Anatomy a distinguished branch of human knowledge.

Whether art or science, anatomy is one of those eminent accomplishments without which no one is able to prosecute his studies with half that pleasure and success which he might in either the animal or vegetable kingdoms. Having been always accustomed to assign it one of the highest and most honourable places among those branches of human knowledge which are styled liberal, we must be excused if we dwell a little in exposing an attempt to convert it to a craft.

25 The liberality of some of its professors.

It is with surprise, and a mixture of regret, that we see a writer of distinguished merit wishing thus to degrade it, and seeking to confine it as well as physiology to that profession which chanced to be his own. The dignity of a science, which he considered as his glory and pride, should have certainly extinguished in a generous mind the low and disgusting policy of his trade. It is indeed with reason that he thinks it unfortunate, "that those who, from the nature of their education, are best qualified to investigate the intricacies, and improve our knowledge of the animal economy, are compelled to get their living by the practice of a profession which is constant employment." We lament the misfortune as much as he can; but we reason not from it in the same way. Instead of complaining that "idle professional men," particularly "of the church, should become philosophers and physiologists as it were instinctively," we are happy to learn that men of enlightened and cultivated minds are thus so readily disposed to assist us; that nature conducts them as it were by instinct; and that happily they enjoy all that leisure which is deemed so necessary for such an undertaking. The genius of some, and the liberal education which they all must have had opportunities of acquiring, by no means impress us with any unfavourable ideas of their aid.

Our author allows them to look through microscopes and examine the red globules of the blood: They may too, he says, view animalcules, and give us a candid relation of what they see; but should not presume to carry their reasoning into a science of which they can know nothing, or hope to throw light on a subject which it is impossible they can understand. But to speak freely, after considering the great physiological discovery of Priestley, with respect to *respiration*, the most important probably, not even excepting that of the *system of absorbents*, that the science has witnessed in the present age, we see no grounds for prescribing such laws or fixing such limits: and although he may treat the illustrious Reaumur and Abbé Spallanzani as nothing more than makers of experiments, and declare a resolution to place no confidence in those which are made by *gentlemen and priests*; he

will not certainly deny that others have as well as he a just right to think for themselves.

Preliminary observations.

Were such sentiments to become universal, it is difficult to say what would be the consequence. In Britain, the law and the church require from their members a formal certificate, that, besides the professional they have also attended some literary class at the university. To their medical classes boys are admitted from the shop and from the school, and may afterwards pass the two colleges of surgeons and physicians, by exhibiting a little skill in their art, or at least by paying the stated fees. On these accounts, being anxious already for the fate of a profession which they respect, and considering the degeneracy to which it is exposed, not they hope the degeneracy into which it is sinking, they should be sorry to see it deprived of that respectability which it may derive from the countenance of men possessing general literature and science.

It is very true, that gentlemen and priests may not be anatomists; and not a few anatomical disputes might seem to insinuate, that persons may be very eminent anatomists without being either gentlemen or priests. Still, however, there is nothing incompatible in those characters; and, were we to judge from their writings, it was certainly a thing of which Bacon, Newton, and Locke, never dreamed, that the study of the priest, or the mere circumstance of being a gentleman, was to blunt their acuteness for physical research, or in after times to affect their reputation as men of genius.

"When men have begun to reason correctly (says Dr Hunter), and to exercise their own judgment upon their observations, there must be an end to delusions. Many doctrines of old physicians and of old women will meet with proper contempt; and the tyranny of empty pomp and mystery of physic will be driven out of the land, and forced to seek shelter among less cultivated societies of men."

If the learned professions wish to be respected, let them respect each other: for our part we esteem them all: and whatever assistance either they or others may afford to physiology, they may be assured that they will not find us anywise disposed to detract from its merit. Divested of prejudice, we value as highly the discovery of Priestley, which explains respiration, as if it had come from Albinus or Haller, and with as much readiness acknowledge obligations to the celebrated painter Leonardo da Vinci, as if he had been a doctor of physic. See ANATOMY, p. 667.

But while we are thus impartial to others, we would not be unjust to professional anatomists. Their learning, their patience, and ardour, have been great; and candour obliges us to assert their claim to the most numerous and important discoveries that have yet been made in physiological science. The pains which they have taken, the prejudices which they have surmounted, and those feelings which they have sacrificed in describing the parts of the dead body, place their labours beyond all praise.

But their discoveries have not been confined to a mere knowledge and description of parts. In the still fabric, just as in a time-piece or a broken orrery without motion, the whole presents a very confused and even an uninteresting appearance. In this case, should the man of reflection happen to ask, where are the organs of the different functions? all would be silence, and

Preliminary observations.

and nothing would be found to make a reply to such an inquiry. The arterial system is relaxed and empty; the muscular fibre cannot be roused; the heart has ceased from its wonted beatings; and the nerve refuses to convey sensations. On this scene the eye of the anatomist could not be expected to dwell long with much satisfaction. Curiosity would induce him to look beyond it, and study the design. He would soon perceive, that to know the uses of the several parts, they must be seen alive and in action. But here new difficulties would arise, and feelings of compassion would exclaim against any farther pursuit. The natural zeal, however, of inquiry, the good of mankind, and the love of science in a generous mind, are not easily resisted.

To his lasting praise, and the singular improvement of true physiology, the anatomist has examined the living body, and has there observed, that all motion proceed immediately from the muscular fibre; that the muscular fibre again derives its power from the nerve, which terminates in the brain; that fibre, and nerve, and the whole system, are nourished by the blood which comes from the heart; and that the waste of blood is supplied by the lacteals, which absorb nutritious matter from the food as it passes along the intestinal canal.

He has also observed, that the blood, which is in continual motion, has a circular course; that other vessels along with the lacteals are employed to absorb; and by means of injection has shown the route of the different fluids as clearly in the dead as they could have been seen in the living subject.

When his eyes have failed in tracing objects that were too minute for unaided sight, he has called in the help of the microscope, and discovered the red globules of the blood, animalculæ in the semen, and the anatomies of the arteries and veins; and when the microscope could lead him no farther, he has had recourse to chemical analysis, and made discoveries equally important in demonstrating the bodies which compose the several fluids and the solids.

Besides these services which the anatomist has rendered to physiology, the science is likewise greatly indebted to him for those various and ingenious methods which he has taken to diffuse his knowledge. Whatever has occurred remarkable or rare, he has studied to preserve either dried or in fluids that resist putrefaction. By corroding the parts which he has injected in a certain acid, he has given an idea of the vascular system, which is at once instructive and elegant. Where it has been necessary to destroy the parts when incapable of preservation, or where the preservation would have been expensive, he has not neglected to represent them in models of wax, or to perpetuate them in accurate casts of lead or of stucco: and, lastly, that the valuable fruits of his labours might not be confined in his room of preparations or to his pupils, he has described most of them in drawings, has multiplied his drawings by correct engravings; he has even published his numerous engravings, and to render them intelligible, has illustrated each with copious explanations.

27
The views of the anatomist often too confined.

From this account it might be supposed that the anatomist has done all that can be reasonably expected from him. If we drew, however, such a conclusion, we might certainly be charged with precipitation. His views have hitherto been too confined, nor have they been directed with all that skill which a ra-

tional and comprehensive physiology would require. As if chiefly guided by the rant of the poet, that "the noblest study of mankind is man," he has cultivated his art principally with an eye to medicine and surgery; and while he has dissected the human body with a tedious minuteness, he has seldom looked into those of brutes but when he has wished to illustrate a theory or establish an hypothesis.

Preliminary observations.

As some apology for such a conduct, there is indeed but little immediate or pecuniary advantage to be derived from comparative anatomy; and those who have heard of the fox and the grapes will readily perceive, that few will be disposed to commend a science which reflects not much credit on their knowledge, and which they are led from sentiments of pride to treat as either contemptible or useless. The declivity tone and affected air of superior discernment being not unusually a very tender part of the character, they often form that mark of distinction which is seldom resigned but with the utmost degree of reluctance. It is, however, allowed, that any opposition from these causes ought not to frighten an aspiring genius. His nobler mind should look beyond pecuniary prospects; and he ought to have fortitude enough to despise the sneers and malevolence of pompous ignorance. The other difficulties which he has to encounter in his own elimination may not be so small.

28
Obstacles in the way of a more liberal study of anatomy.

In seeking to enlarge the field of inquiry, he will soon experience that he wants a language, or at least a nomenclature fitted to express the different objects which must necessarily occur in his researches. He will find too that he wants those proper classifications of the animal kingdom, which are equally necessary both to abridge and direct his labours.

29
The want of a nomenclature.

The first nomenclature of the anatomist was formed upon the dissection of brutes; and most of its terms, as the *rete mirabile*, are now useless, or tend to mislead those who employ them in their dissections of the human body. The few of its parts which still are retained, as the different names and divisions of the gut, are much more applicable to the usual appearances in certain quadrupeds, than to any thing which we meet with in man.

30
Origin of the anatomical nomenclature.

This first nomenclature declined with the studies which gave it birth, and with the decline of that superstition which permitted no other studies of the kind. Since the days of Vesalius the human body has been chiefly dissected; and the nomenclature which has thence arisen, and has since been assuming the form of a language, if adapted at all, is peculiarly adapted to that subject. Were we now therefore disposed to examine the internal economy of animals in general, we should see at once that the present nomenclature is as ill suited to comparative anatomy as the former nomenclature was to the dissection of the human body. The several facts which confirm this assertion are but too numerous. To give one or two: In a late work, *The Physiology of Fishes*, the celebrated author is obliged to inform his reader in a note, that when he makes use of the following terms, superior, inferior, anterior, and posterior, the fish is supposed to be standing erect, in the attitude of man: and in his ingenious *Contemplation on Nature*, Bonnet, besides the absurd practice of calling nerve by the name of marrow, has been pleased to observe that in certain insects the spinal marrow

row

Preliminary observations. row is not in the spine, but in the opposite side of the body, running longitudinally along the breast.

31 Defects of the present nomenclature. Applying occasionally this nomenclature to the small number of birds and quadrupeds which we have dissected, it was much strained with respect to their skeletons. Even forced analogy could not bring it to express many distributions of the nerves and blood vessels; and when it was employed in naming the muscles, in most cases it turned out to be useless or absurd.

We were first led to observe its defects on hearing of the nameless bones of the pelvis, called the os ilium, the os ischium, and the os pubis, united behind by an os sacrum, which is tipped with a coccyx or bone of a cuckoo: we thought it likewise somewhat remarkable to find a goat, a boat, and a conch shell, among the external parts of the ear; and within the tympanum a hammer and its shaft, a stithy, a turnip, and a periwinkle. But these defects were most seriously felt in raising the different muscles of a dog, and comparing them severally with Albinus's tables. These tables and muscles, to our great surprise, did not reflect that mutual light upon one another which we expected. To obtain here more accurate ideas we got the comparative myography of Douglas. At one glance the etymological table of this work demonstrated the confusion and the imperfection of the nomenclature. In his, as in other books of myography, the muscles are explained by describing their origins, insertions, and uses: but the table shows, that their names are never, excepting only in a few cases, derived from any of these three circumstances, which in every description are uniformly noticed in all muscles. Their names on the contrary are frequently taken from their particular form and appearance in the human body, or from those circumstances which are constantly varying in every animal; just as if muscles of the same origin, insertion, and use, should in all animals have a similar colour, a similar mode of insertion and origin, a similar composition and variety of parts, a similar course and direction of fibres, a similar figure and shape, a similar passage through certain places, a similar proportion with respect to one another, or should be formed of a similar substance.

If we pass to the membranes, as expressed in this nomenclature, we shall not discover that their names are more philosophical. A periosteum covers the bones, a pericranium the skull; the cavity of the thorax is lined with a pleura, that of the abdomen with a peritoneum; and what is surely somewhat remarkable, bones which are hollow have a periosteum on their inside: the membranes in the skull are by way of distinction denominated *mothers*; the one which lies next to the cranium is the dura mater or hard-hearted mother, while that which immediately enwraps the brain is the mater pia or the affectionate mother.

Of all the terms, however, that occur, the cavity of the skull contains the most extraordinary collection: we there meet with a Turkish saddle and with the feet

Preliminary observations. of a sea-horse, with a ring, with a lyre, with a sickle, with a bridge, with a writing pen, and a wine press. A few of these names belong to the substance of the brain itself: where one part is called from its hardness the calous body, another from some fancied analogy the medullary substance, and a third from being on the outside is named the corticle, and from its colour the cineritious. These are not all: there are besides footstalls of the cerebrum and cerebellum; the thighs and arms and fore and hind legs of a grand division, the medulla oblongata; there is also a vault and two or three pillars, one pair of striated bodies, two beds, and a couple of horns; some cavities which, from a supposed resemblance to stomachs are called ventricles choroid coats; two bodies, named from the olive, two from a pyramid, and one from a vine, which is chiefly remarkable for having once been thought the residence of the soul. At some distance in the cerebellum we are however pleased to meet with a name that is somewhat elegant, the *tra of life*. In this there is a degree of refinement, which must strike one as it comes unexpectedly. The following names are in the lowest style of obscenity: they are wormlike and mamillary processes, they are nates, testes, an anus, and a vulva; which, in order to save the blushes of our readers, we shall leave in the language in which they were conceived. A singular part is placed immediately under a funnel, and is named from its use the pituitary gland; it was meant originally to secrete a phlegm, but it holds that office now as a sinecure (B).

Ridiculous and whimsical as many of these appellations are, they generally have some allusion to their subject, and are by no means the most exceptionable in this nomenclature. The names of discoverers which have been imposed upon various parts, contain no description at all; and the only purpose which they can serve is not to promote the interest of science, but to immortalize the anatomists. As many of those have not been more than insensible to fame, they or their friends have taken the freedom to introduce parts to our notice, not by telling us what is their nature, but by demonstrating who was the first that observed them. Upon reading therefore the catalogue of names that occur in anatomy, one would imagine that many of these ingenious discoverers had supposed themselves not the discoverers but the inventors of several parts in the animal economy. In our vascular system is the ring of Willis, the vein of Galen, and the large wine press of Herophilus. We have in our brain the bridge of Varolius; and in our nerves we possess the property of various diversers. The holes of Vidius, and the caverns of Highmore, are in our bones; some small muscles in the sole of our foot is the fleshy mass of Jacobus Sylvius; a part of our eye is the membrane of Ruyfch; and in those cases where they are to be found, Couper lays claim to particular glands; two canals from our mouth to our ears are the tubes of Eutachius;

(B) That our readers may judge whether or not these names be fairly translated, we subjoin the originals here in a note. In the ear, *tragus, scapha, concha, malleus, incus, stapes, cochlea*: in the cavity of the skull, *sella Turcica, pole hippocampi, annulus Willisii, psallides vel lyra, sulcus duræ matris, pons Varolii, calamus scriptorius, torcular Herophili, corpus callosum, substantia medullaris, substantia corticæ vel cinerea, pedunculi cerebri et cerebelli, femora, brachia, crura anteriora et posteriora medullæ oblongatæ, fornix, corpora striata, thalami nervorum opticorum, cornua nervorum opticorum, corpora olivaria, corpora pyramidata, glandula pinealis, arbor vitæ, tulercula mamillaria, appendices vermiformes.*

Preliminary observations.

* Morfus diaboli.

³² The persons most apt to perceive these defects.

³³ Hints respecting a new nomenclature.

chilus; the duct of our pancreas is the right of Virginius; Poupart has a ligament almost in our groin; a lobe of our liver belongs to Spiccius; and the female would certainly stare at being told, that among the distinguishing marks of Herfex are the tubes of Fallopius, a tench's mouth, and several veilliges of the devil's teeth.

The man who will readily observe the effects of this nomenclature is not he who has learned it already, and who no longer is acquiring his ideas through its imperfect and confused medium; nor is it he whose studies are confined to the human body, the particular subject on which it was formed: He who will sensibly feel its inconvenience is the young anatomist, who must receive his knowledge through its channel, commit its vocables to his memory, and use them afterwards in recalling his ideas. Another who must soon perceive its failings, is he who engages in comparative anatomy, and who is anxious to extend his views beyond that which the foolish indolence of conceited bombast has called the *microscopium*. A third will be he who has remarked the numerous synonymes which different authors have thought themselves warranted to substitute in place of the old terms: for their repeated attempts at amendment are a strong proof of that estimation in which it is held by the anatomical writers in general: And, lastly, that man cannot hesitate long to pass upon it a condemnatory sentence, who, like Wilkins, Locke, Condillie, and Reid, is a person of extensive and profound reflection, who is well acquainted with the intimate connection between accurate expressions and accurate ideas; who knows how much the improvements of language are able to facilitate the progress of science; or who has experienced the wondrous effects that have already resulted from the example and labours of Linnæus, and particularly from the new nomenclature in chemistry, which can hardly be too much valued and admired.

Our intention here is not to suggest a particular plan for any new anatomical nomenclature: the state of our knowledge may in this respect be yet too imperfect, and perhaps it may be necessary to see more of the animal economy, before we should venture on such an undertaking. We may however, in general, observe, that this nomenclature, like the languages of nations, ought not to be formed with any view to an individual, a species, or genus; and after that be carelessly extended by fanciful analogies to new objects, and from these again be extended to others; thus making metaphor to spring out of metaphor without end, until the original figure be lost, and revived and lost again, times without number. It ought to contain as many as possible of these terms which, understood in their primary sense, might apply to the whole animal kingdom and living bodies, without any metaphorical expressions, if, in describing the tastes and colours, such expressions can be avoided. Instead of the words anterior, posterior, inferior, and superior, which are perpetually shifting their meaning with a change of attitude, it ought to have words of one constant invariable import, expressing the regions of the head and the back and their two opposites. These terms, with right and left, would be found in anatomy to answer nearly the same purpose that the degrees of longitude and latitude, or the points of the compass, do in geo-

graphy. Every part would then be considered as lying within or as pointing to six different regions, the right, the left, the head, the back, and their two opposites. If more particular descriptions were wanted, the definitive terms might then be taken from the more immediately surrounding parts; thus giving an account of the ethmoid bone, D'Azzy borrows the definitive words from the regions of the cranium, the sinu-occipital, basilar, facial; and occipital; or from the regions in immediate contact, the cerebral, palatine, nasal, and sphenoidal.

If an object attainable, this nomenclature too should be derived from one origin, and not like the present be a wild incoherent Babelian gibberish of a number of mixtures. It ought to aim at conveying its ideas with clearness and precision, and yet fully, concisely, and promptly. In point of simplicity it ought to study the ease of the memory in receiving, retaining, and in recollecting. To prevent a needless multiplicity of terms, it ought to avoid puerile minutiae, which serve no end but to render description tedious and confused; it ought to avoid such trivial divisions, as those of the gut into duodenum, jejunum, ileum; or those of the artery into subclavian, axillary, brahial; and, lastly, it ought to be formed on a plan containing certain rules or construction for giving names not only to parts already discovered, but to those parts which are still unknown, or which distinguish individual and species.

In imposing names, it might perhaps be of some advantage to examine not only together, but separately, the great constituent parts of the system; as the bones, the ligaments, the cartilages, the muscles, the membranes, and the glands; the nervous, the sanguiferous, and absorbent systems; and all these with their properties and uses perspicuously arranged. How far a regularity in composition, and an uniform variety of terminations, might be of use in this nomenclature, can best be conjectured from their great importance in the new philosophical language of chemistry.

It has been observed, that such a nomenclature, to encourage and assist the comparative anatomist, is still wanting; and it also was remarked, that we yet are unacquainted with proper classifications of animals, peculiarly fitted to direct and abridge the anatomist's labour, and to satisfy the inquiries of the physiologist.

Our present physiological arrangements are, like our present nomenclature, principally suited to the human body. To take our instance from the celebrated Haller, he begins his *Outlines* with the simple fibre, and the cellular texture, of which he is anxious to compose as many of the folds as he can. He then proceeds to more of the organs, describing with great erudition and care their different uses and structure in man. These organs, however, which he describes, and those analogous with respect to their structure, are confined to a part of the animal creation. As different classes of the animal kingdom have with similar functions varieties of organs, and as one function is consequently performed in different ways, it is evident that organs ought not to form the general divisions in any physiological system of arrangement, because we should then have a new arrangement for every new species of organs. Of this truth Haller and others have not been ignorant. They have also divided their subject into

³⁴ The present physiological arrangements too confined.

³⁵ Two kinds of arrangement: according to the functions, or according to their organs.

functions;

Preliminary observations. functions; but still they are functions in the manner performed by the human body. This body has engrossed so much of physiology, that we often see the functions explained with scarcely any allusion to their organs; as these are supposed to be always the same, and already known from the usual dissections.

36
Haller's physiology refers chiefly to the human body. Haller's physiology is professedly that of the human body. His conduct here was seemingly the effect of general custom: it did not arise from any contempt of comparative anatomy. There have been few who esteemed it so highly, who have studied it more, or applied it so skillfully. He declares that there are many parts of our bodies whose functions can never be fully explained, unless we examine their structure in quadrupeds, in birds, in fishes, and even in insects; though he therefore had dissected of human subjects to the number of 350, yet the number which he dissected of brutes, and what is more, dissected alive, was much greater. Numerous, however, as were his dissections, they were too confined for general physiology. That requires a range more extensive; and, to shorten the labour different classifications of animals from any of those to be usually met with. This assertion hardly needs a proof.

37
Zoological and physiological arrangement. There is nothing more certain, than that were the anatomist to dissect animals as they occur in the system of Linnæus, or any other naturalist, his toil would be immense, and the knowledge which he thence would acquire of functions would scarcely be found to bear to it even the smallest proportion. By this observation we mean not to object to those ingenious classifications which Linnæus and others have employed to facilitate the study of zoology. All their classifications may be useful; and many display that extent and clearness of comprehension, that distinguishing acuteness, and that laudable ardour for the interest of science which ought to render their authors immortal, and intitle them to the gratitude of future ages. Yet these systems are formed with a view different from that which principally ought to direct the physiologist. They were meant to contain a full enumeration of the objects of zoology so far as known; to exhibit them arranged in different classes and subordinate divisions, according to such obvious and distinct marks as might strike at a glance, or appear on a cursory examination. To him who is entering on the study of zoology, they show at once the extent of his subject; they elevate his mind by the grandeur of the prospect; and when better employed than in pleasing the fancy or in rousing the rapturous feelings of a poet, they draw his attention to those significant and marked signs in which the language of nature is written. They assist his judgment in the art of arrangement, and give to his memory a power of recollection which it had

not before. To the natural historian they perform a service equally important, if not essential, to his undertaking: to him they supply the place of chronology; and instruct his readers by the chain of connection which they give to his thoughts, and by that perspicuity which they invariably bestow on his language.

39
Difference between them. These arrangements, however, with all their advantages, are not the arrangements which the physiologist would wish the anatomist to observe in his dissections. They are certainly useful in studying the manners, dispositions, and habits of different animals, and all that part of the outward economy which indicates something of their wisdom and design. But they little illustrate that internal structure on which this outward economy is founded, or tend to explain the more secret functions which, not depending on the will of the creature, only display the power and omniscience of him who made it. This consequence is easily conceived, from considering the difference between zoology and what has been here defined physiology. Zoology is chiefly led to examine the animal kingdom as it usually presents itself to the eye, including a great variety of objects; physiology only that single part of the animal economy which is chiefly made known by anatomy and chemistry. Zoology has been wont to divide its kingdom into so many classes or orders of animals; physiology would naturally divide its economy into so many functions. Zoology has subdivided its classes by certain obvious and exterior marks, as the teeth and the claws; physiology would naturally subdivide its functions by the many varieties of those organs which are destined to perform them, as the different kinds of lungs and of stomachs. Zoology but cursorily mentions the functions as forming a part of the history of animals; physiology takes notice of animals only when they are of use to illustrate its functions. From this comparison it will readily appear, that things which are primary in a zoological will often be secondary in a physiological species of arrangement; and that things which are primary in a physiological will often be no more than secondary objects in a zoological. This is very conspicuously the case in one of the grand divisions of Linnæus into mammalia, where the important secretory organs of the milky fluid are noticed only, like the colour of hair or the length of a tail, as a good outward mark of distinction; and likewise in the excellent table of D'Aubenton, where the function of digestion is not even alluded to at all; although he had complained that there was more of art than of nature in the common arrangements, that classification by outward marks had confounded things of a different structure, and that the lesser divisions should be made only by marks relating to the functions.

Preliminary observations, 39 Daubenton's arrangement.

A N I M A L S.				The most part without a Head.	
With a Head.		Without Noftrils.		Without Noftrils.	
Noftrils.		Ears.		Without Ears.	
Two ventricles in the Heart.		One Ventricle in the Heart.		The Heart variously formed or unknown.	
Warm Blood.		Blood nearly cold.		A whitish Fluid instead of Blood.	
Inspiration and Expiration of the Air at short Intervals.		Inspiration and Expiration of the Air at long Intervals.		Admission of the Air by Gills.	
Viviparous.		Oviparous.		No apparent Entrance to admit air.

Preliminary observations.

Preliminary observations.

It is plain from this table, and from what we have mentioned concerning Haller, that it would be injustice to anatomists and naturalists to say they have never paid any attention to the physiological modes of arrangements. It can only be said that they have not paid to them all that attention which they deserve; and that no general physiological system of arrangement, excepting D'Azyr's, has, so far as we know, been yet attempted.

of absorbents. D'Azyr has mentioned a great many more. He particularly recommends Perrault, Du Verney, Collins, and D'Aubenton, on Birds; Quindrups; Chirac, Roerh, and Fouchon, on Reptiles; Ray and Woodhouse, on Arted, the Goums, and Brouffinet, on Fishes; Swammerdam, Malpighi, and Reaumur, the Geoffroys, Bonnet, and Lyonnet, on Insects; and, lastly, the curious researches of Will's, Ellis, and Donati; of Trembley, Baker, Bafter, and Boadfeh; of Fofskal, of Adan'on, of Muller, Palla, Spalanzani, and Diquemare, concerning Worms, Zoophytes, and Polyps. Where any errors are to be corrected, or where any deficiencies are to be supplied, it is needless for us to observe that recourse must be had to new examinations and to new dissections, where it may be of some use to attend to the foods of animals, to their places of abode, and their modes of life, as circumstances leading to some internal varieties of structure. To the list of authors we might have added Camper on Fishes; and we should not forget the excellent writings of D'Azyr himself, whose table of physiological arrangement is a work of merit that bespeaks reflection, ingenuity, and labour, and which follows here, with only a small variation in form.

Preliminary observations.

40 Whence materials might be collected for a physiological arrangement.

How such an arrangement ought to be made is easily described, though by no means very easily executed. It needs not a proof that functions should form its primary divisions; that its subdivisions should be the varieties of these functions; that the whole should be both distinguished and explained by the kinds and varieties of those organs, by which they are performed; that the descriptions of these organs might partly be collected from the several works of natural historians and comparative anatomists, as from the dissections of the French academy, from numerous fragments of the *Curieux de la Natur.*, from the collections of Blasius and Valentini, from the writings of Haller, from the works of the celebrated Hunters and Monros, from the publications of Hewson and Cruikshank, and those who have lately been making discoveries in the system

41 D'Azyr's arrangement.

A TABLE of the FUNCTIONS or PROPERTIES of LIVING BODIES.

- | | | |
|-----------------|------------------|------------------|
| 1. DIGESTION. | 4. RESPIRATION. | 7. GENERATION. |
| 2. NUTRITION. | 5. SECRETION. | 8. IRRITABILITY. |
| 3. CIRCULATION. | 6. OSSIFICATION. | 9. SENSIBILITY. |

Every body in which one or more of these functions are observed is to be considered as possessing organization and life.

1 DIGESTION.	Living Bodies	Which have	One or more stomachs, easily distinguishable from the œsophagus and intestinal canal,	Man. Quadrupeds. Cetaceous animals. Birds.
			A stomach distinguishable only by certain expansions from the œsophagus and intestinal canal,	Crustaceous animals. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called.
			An alimentary canal, not distinguishable into œsophagus, stomach, and intestines,	Insects. Worms. Zoophytes.
			Neither stomach nor intestines,	Plants.
2 NUTRITION.	Living Bodies	Whose nutritious juices are absorbed	By vessels beginning from internal cavities,	Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called. Insects. Crustraceous animals. Worms.
			By vessels opening upon the external surface,	Plants.

Preliminary observations.

Preliminary observations.

3
CIRCULATION.

Living Bodies	With blood	Having a heart with two ventricles and two auricles,	{ Man. Quadrupeds. Cetaceous animals.
		With one ventricle divided into several cavities and two auricles,	{ Birds. Oviparous quadrupeds. Serpents.
Living Bodies	With a whitish fluid	With one ventricle and one auricle,	{ Cartilaginous fishes. Fishes properly so called.
		Whose heart is formed of one longitudinal vessel, tuberos and contractile, in which there is a whitish fluid instead of blood.	{ Crustaceous animals. Insects. Worms. In some crustaceous animals there is observed something resembling a heart.
Living Bodies	With juices	In which no heart has been yet observed, but only vessels filled with juices of a nature different from that of blood,	{ Zoophytes. Plants.

4
RESPIRATION.

Living Bodies	Which respire	By lungs free from all adhesion, and spongy,	{ Man. Quadrupeds. Cetaceous animals.
		By lungs free from all adhesion, vesicular, and muscular,	{ Oviparous quadrupeds. Serpents.
Living Bodies	Which respire	By lungs adhering to the ribs, and provided with appendages,	{ Birds. Cartilaginous fishes. Fishes properly so called.
		By gills of different forms,	{ Crustaceous animals. Insects. Earth worms.
Living Bodies	Which respire	By stigmata or holes in different rings,	{ Aquatic worms. Plants.
		By an opening called trachea, or by external fringes,	{ Plants. Polypes.
Living Bodies	Which respire	By tracheæ,	{
Living Bodies	Which respire	In which there have been discovered neither stigmata nor tracheæ,	{

5
SECRETION.

Living Bodies	{	There are no bodies in which secretions are not carried on.
---------------	---	---

6
OSSIFICATION.

Living Bodies	Whose skeleton is	Internal and osseous,	{ Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents.
		Internal and cartilaginous,	{ Fishes properly so called. Cartilaginous fishes.
Living Bodies	Whose skeleton is	External and corneous,	{ Perfect insects. Lithophytes.
		External and cretaceous,	{ Crustaceous animals. Shell fish. Madrepores.
Living Bodies	Whose skeleton is	External and ligneous,	{ The greatest part of Zoophytes. Plants.
		Which have no skeleton,	{ Insects in their first state. Worms. Polypes.

Preliminary observations.

Preliminary observations.

7 GENERATION.	Living Bodies	Which are	Viviparous,	Man. Quadrupeds. Cetaceous animals.
			Oviparous, whether the evolution of the eggs takes place within or without the female.	Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called. Insects. Crustaceous animals. Worms. Plants.
			Which propagate by slips,	Worms. Polypes. Plants.
8 IRRITABILITY.	Living Bodies	Which have	A body muscular or contractile,	Greatest part of insects in the first state of their transformation. Worms. Polypes.
			Muscles covering the skeleton,	Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called.
			A skeleton covering the muscles,	Perfect insects. Crustaceous animals.
			No muscular power; no spontaneous movements,	Plants.
9 SENSIBILITY.	Living Bodies	Which have	Nerves and brain easily distinguishable from the spinal marrow,	Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called. Insects.
			Nerves and brain scarcely distinguishable from the spinal marrow, In which there have not yet been discovered nerves or brain, or spinal marrow,	Crustaceous animals. Worms. Zoophytes. Plants.

42
Difference between mineral, vegetable, and animal.

The above table, which has its divisions marked by the functions, and their kinds and varieties by the kinds and varieties of those organs by which they are performed, differs considerably from a zoological. Borrowing its several marks of distinction from internal characters, it more clearly demonstrates the difference between the mineral, vegetable, and animal, than any system that attempts to arrange by outward appearances. No minerals, whatever be their forms or the regularity and beauty of their figures were ever said to possess any thing like organs of nutrition; and however frequently some may recover their lost shapes, they are never supposed either to produce, or assist in producing, their own kind by generative powers. And no plants, however much may be said of animals that want a nervous system and a heart, and are

fixed, without the power of locomotion, to one place; we say no plants, though some may represent a few of the simpler effects of sensation, and others may be free to float through the ocean, were ever said to discover any signs of voracity, to possess any thing resembling a stomach, to distend their body by swallowing their food, to apply their food to the mouths of absorbents opening internally; and when the nutritious juices were extracted, to eject it *in cumulo*. It has been said that zoophytes present similar phenomena. But what are zoophytes? One half of their name would imply that they are animals, and another half would insinuate that they are plants. D'Aubenton reasons with clearness on this subject. True, says he, the greatest part of them are branched like plants, and like plants are composed of concentric circles. Some have a soft exterior substance which is called, bark, and a hard interior which

Respira-
tion.

which is called wood. Along their branches, and at their extremities, they put forth vesicles which are feable buds; and when a part falls from the whole, it is sufficient, like a vegetable slip, to produce a zoophyte: but do these appearances prove that they are plants?

If ramifications constitute a plant, then many crystallizations will be plants; the frostings of frost on our windows will be plants; the silver tree of Diana a plant; our veins will be plant, our arteries plants; and our very feet which ramify into toes, and our hands into fingers, will have some title to be called plants. The truth is, ramification is not universal in the vegetable kingdom; and although it be general, it is no more peculiar to plants than swimming is to fishes, or flying to birds. If concentric circles constitute a plant, some bones of animals will then be plants, and some minerals must also be plants. The wood and the bark are only two metaphorical expressions, which with equal propriety might have been used of the bone and pericorium. But once suppose the zoophyte a plant, it was natural to carry on the analogy and certainly necessary to have it provided with wood and bark; though it must be allowed that a corneous substance is not what we commonly mean by bark, nor an evidently hard calcareous substance what we mean by wood. The small vesicles, except in appearance have no similarity to buds or fruits: they are the residences of small polype, to whom the whole structure has been owing, by whom the whole either is now or has been inhabited, and to whom it answers the same purpose as the shell does to testaceous animals.

43
Difference
between
living bodies
and
machines.

After thus endeavouring to point out the boundaries between the mineral, the plant, and the animal (A), before we begin to treat of the functions, we must also take notice of another distinction; the want of which has occasioned much unnecessary trouble, and has given rise to not a few ridiculous disputes. This is the distinction between living bodies and some ingenious contrivances of art, which are called machines. It has not been asserted that any machine can either grow or propagate its kind; that it can assimilate the particles of matter that come in contact; that it is able to repair the injuries which it may suffer; that it can accommodate itself to circumstances, can create heat when the cold is keen, or cold when the heat becomes too violent: yet it has been supposed, from established prejudices, and from the successive evolution of parts in plants and in animals, that there is an analogy between a machine and a living body. The living body has been called a machine; and notwithstanding the acknowledged truth of that observation so often repeated since the days of Hippocrates, That the whole is a circle, that nothing is first and nothing last in the

animal economy, we are still talking as if living bodies were nought but machines: we are still reasoning as if their parts had existed in succession, had acted in succession, were combined in succession; we are still seeking for what is prior and what is posterior, for what is derived and what is original in point of structure, as if we were examining a work of art; we speak gravely of the viscera, of the thorax deriving a coat from the membranous pleura, the abdominal viscera from the peritonium, and the branches of nerves deriving a pair from the dura and pia mater of the head; we argue with people who maintain that fasciæ are nervous expansions, and the muscles themselves but nervous productions: and although we be hardly able to conceive how the brain could be nourished without blood drawn from the heart, or the heart move without the assistance of nerves from the brain, we are still disputing about which was prior and which was posterior in point of existence; a dispute that will probably terminate as soon as that of the ancients, whether the first eggs were from birds, or the first birds were hatched out of eggs.

Preliminary
of fer-
vations.

44
The vital
organs
seemingly
coeval in
point of ex-
istence.

These dark and inscrutable mysteries of nature we presume not to explain: they point out almost the creative hand, and bring us almost into the immediate presence of that Being by whom we live, move, and exist; and before whom the truly feeling and elevated mind is less disposed to examine than adore. We are only to observe, that from this coeval formation of parts which the microscopic part of anatomy has often distinguished from their evolutions, and from this mutual dependance of organs one on another, we are left at freedom to begin at any part of the circle, and treat of the general properties and functions of living bodies.

45
Functions
form a cir-
cle.

We now venture on a rude sketch of the order and manner in which these properties may be explained, and in which the facts in general physiology may be afterwards arranged. Another opportunity may produce something more full and correct. In the present sketch, many imperfections will no doubt be found; we already are able to foresee many from our own inability to treat the subject according to its merit. And perhaps the reader, who is possessed of temper and candour, will impute some to the newness of the plan, and the present infant state of the science.

Without blaming the arrangement of D'Azyr, whose genius and labours we shall always respect, we have been induced to adopt the following, from those reasons with which the reader is now to be acquainted.

Attending minutely to a living body, which already has escaped from the seed, the egg, or membranes of the parent, which is wholly disengaged from the placenta,

(A) It is curious to observe how careless we are in annexing precise ideas to our words. Bonnet supposes that in some world more perfect than ours, the rocks may be organized, plants may feel, brutes may reason, and men may be angels. In this passage the form was all that seems to have entered into his idea of the man and the brute, and to new was his notion of a perfect world, that one who believed in the metempsychosis, would naturally imagine that he here had been fancying a state for the damned, where angry heaven was to fetter the angel in the form of a man, a man in that of a brute, a brute in that of a vegetable, and a vegetable in that of an uncouth rock. How much to be pitied would the creatures be that reasoned and felt, and were at the same time more incapable of moving than an oyster or a limpet!

Preliminary observations.

46
The arrangement of functions in this article.

placenta, and depends for the future on the operations of its own organs (B), we may observe, that in order to live, it must be allowed the free use of air, as applied by the organs of—*Respiration*.

That, in order to grow, it must have likewise a supply of food, which is a substance somehow adapted to its constitution; and which, on being received into the system, is

- Prepared by—*Digestion*,
- Taken up by—*Absorption*,
- Distributed by—*Circulation*,
- Assimilated by—*Nutrition*,
- And the whole carried on by means of—*Secretion*.

We next may observe, that in order to enjoy the free exercise of these functions, it must be secured from the more common and external injuries of its situation; and that this is done by certain integuments originally produced, and when it is necessary, afterwards renewed by that function; which, till we receive a new nomenclature, we shall venture to call by what may be rather an uncouth word—*Involution*,

We again may perceive, that these functions are all dependant on a general principle—*Irritability*;

By which the system is rendered by stimulants susceptible of—*Motion*;

Accommodates itself, to different circumstances by means of—*Habit*;

- Alters its shape by successive—*Transformation*;
- Produces the species by—*Generation*;

And when the business of life is finished, is, after many a languid affection from the influence of—*Sleep*,

At last subjected to the general fate of all living bodies—*Death*.

These we imagine are the general properties of living bodies; and such is the order in which we are now to take a short and cursory view of them.

SECT. I. *Respiration*

Is that function by which air is brought into

the system, and by which it is prepared in particular organs, that in some respect succeed the placenta in the general economy. For as any interruption of the usual intercourse between the placenta and fetus in ovo proves soon fatal, so when that communication naturally ceases, and the new one succeeds between the lungs and external air, it is likewise found, that any preternatural interruption of this last is in all living bodies presently attended with various symptoms of increasing languor, and in many with an almost instantaneous death.

So essential is respiration to the system, that snails, chameleons, and some other animals, can live for years up a air alone. We have seen a chameleon that lived and was vigorous for twenty two months without any food, and which might have continued to live much longer but for an unfortunate bruise by a fall.

Other phenomena equally demonstrate the importance of air to the living body. The frog leaps away wanting its heart; it survives the loss of the greatest part of its spinal marrow. Without its head, it lives for some days, and its heart continues to circulate its blood (c). Spalanzani took one from the back of a female, cut off his head, and after performing this whimsical experiment, saw the gallant return to his mistress grasp her in his arms, and finish the task which he had begun: And Borelli found, that eels and serpents, though their bodies be opened, and the whole of their viscera be taken out, are able to move for a day after; and yet notwithstanding, in all these animals, the life is observed to be suddenly extinguished when the all-vivifying air is excluded. Even the smallest insect has died, and the plant lost its vegetative power, when retained for any while in a vacuum. The fish itself, when placed under the exhausted receiver, has started anxiously to the surface of the water in quest of fresh air; and finding none, has sunk to the bottom and expired in convulsions.

Preliminary observations.

47
Respiration defined.

48
Its importance to living bodies.

If

(B) To give a general view of the manner in which living bodies are nourished and supported in the egg and uterus, and before they begin to depend entirely on their own organs, we have subjoined a Plate (see Plate CCCXCI.), representing embryos of various kinds. The three first figures are from Swammerdam: the first is the membrane containing the insect, the second the membrane after the escape of the insect, the third is the insect itself, fed by absorbents, opening on different parts of the body.

The fourth, fifth, and sixth, figures, are from Grew: the fourth is a bean, spreading its seminal roots into the lobes. In the fifth, and sixth the lobes of the seed are seen converted into seminal leaves.

The seventh to the twelfth represent the transformations of the chick in ovo: the first of these figures is from Aquapendens: the rest are from Blaius, who got them from Malpighi.

The remaining figures are all from Aquapendens: the two last represent a fish that is sometimes oviparous and sometimes viviparous.

Plants and animals are here observed spreading their roots in a similar manner. The proper proportions are overlooked, not being necessary to convey the idea which is here intended.

(c) "Two days (says Dr Monro) after cutting off the head of a frog at its joining with the first vertebra, I found it sitting with its legs drawn up in their usual posture; and when its toes were hurt it jumped with very considerable force. Its heart likewise continued to beat about forty times in a minute, and so strongly as to empty itself and circulate the blood.

"In several frogs, after cutting off the back part of the six undermost true vertebra, I took out all that part of the spinal marrow with the cauda equina which they cover. The lower extremities were rendered insensible to common injuries, and lay motionless: yet the frogs lived several months thereafter, and the wounded part of their backs cicatrised, and the bones of their legs which I fractured were reunited, the blood circulating freely in their vessels." *Experiments on the Nervous System*, made chiefly with the view of determining the nature and effects of animal electricity.

Respira-
tion.

If objections should be made to these trials performed in a vacuum, if it should be said that under the receiver the thrivelled fruit swells and turns plump, that the body of the frog is strangely inflated, that its turged eyes grow prominent in its head, and that thin phibias corked full of air are broke by its expansion; still there are facts which do not admit of the like equivocal interpretation. All living bodies will die in the air which they have respired; and when ice covers the whole of the water, many of the fishes are known to perish: or if an opening be made in the ice, to hasten to the air, and rather than retire, quietly suffer themselves to be caught.

49
See in
exceptions.

To this general dependence of life upon respiration, there occur but few things like an exception: these are some serpents and worms and crustaceous animals found alive in the hearts of the stones, some insects that were found in wood, and a number of toads which in different places have been taken from the hearts of trees and of rocks, where they left an impression, and where they were supposed in some cases to have lived for centuries without air. These facts, real or pretended, have been the cause of much speculation. Some philosophers, who imagine that nature is always obliged to act agreeably to those ideas which they have already formed of her laws, are, notwithstanding the high authorities by which some of these facts are attested, disposed to doubt them. General analogy, which regularly opposes singular phenomena, is upon their side; and without her concurrence, they will grant existence to no living body that will not submit to the old established modes of respiration. Others again, who would not presume to dictate for nature, who have long experienced that she is not forward to obtrude her secrets, and who can believe that she may have still some to communicate, consider these facts as something new which she means to impart; and as one of the instances where she seems to deviate from general analogy in adhering to her grand accommodating principle by which she fits every living body for a certain range of varying circumstances.

50
Animals
included in
stones, &c.

These last, receiving the facts as sufficiently authenticated, have studied only how to account for them. When stones therefore were thought coeval with the world itself, they supposed their toads to have sprung from the ova that were scattered through the earth at its first formation; they did not recollect, that if the earth must have existed before those ova could have been sown, and that if the stones were coeval with the earth, the ova could not have entered their substance. When they afterwards learned that the consolidation of stones is an operation still carried on in the mineral kingdom, they acknowledged their ova to be less ancient, but did not perceive that all these ova involved suppositions that cannot be admitted by sound reason. For how was an ovum to grow without air and without food? and how particularly was it to grow with such a force as to make an impression in a solid rock? This would imply a power of expansion scarcely to be equalled by gun-powder, and which we ought not to be rash in ascribing to the nutritive effects of abstinence and nothing. Were it not for the toad, the expansion itself might have found a solution in a *theory of the Earth*, which has cast all its stones in a foundery under

51
Opinions
on this sub-
ject.

the water, where the moisture might have rendered them apt to be formed with numerous cavities.

Respira-
tion.

Perhaps the way to remove these difficulties concerning the toad, would be to ascertain its mode of existence in the heart of the stone. Suspecting that the air communicated somehow with the solitary cell, we procured a toad that was crawling out from its den in the evening. It was put into a glass just large enough to hold it with ease. The mouth of the glass was filled with cork sufficiently close to retain water; the glass was then laid on its side, and the animal respired for several days without discovering signs of uneasiness: but supposing that air might still be admitted, the cork received a covering of wax, and the animal died ten hours after.

From this experiment, and the fate of toads when put under an exhausted receiver, from an air passage in the crust of chrysalids, from the porous texture of the white speck, or the opening which the snail leaves in the membrane that is spread over the mouth of its shell, we were led to think on d'Aubenton's remark, that the inclosed toads might have breathed, and that the wood has been always cleft, and the stone broken, before it was shown how the external air was excluded †.

† Encyclo-
pedie Me-
thodique,
tom. 2.
partie 2.
p. 610.

On farther reflection, our own experiment appeared inconclusive; and d'Aubenton's remark, after close examination, seemed not entitled to much attention. He would have it supposed that a toad is lurking in every block of stone and of wood; and on this supposition would have an inquiry to be regularly made, whether or not there be any communication between this supposed animal and air; because, when the stone or wood is in fragments, the attempt to disprove such communication is in his opinion impossible.

But are we certain that the admission of external air would remove the difficulty? We are not so positive now as we were upon this subject. In the summer months, we recollect to have drowned frogs which were living in the fields, by keeping them some hours under water: but if we allowed them to rise to the surface, and respire at pleasure, they became at last so accustomed to that element, that if the temperature was not much above that of spring-water, they lay in the bottom not only for days but for weeks together.

In the winter season, it is well known that frogs are sometimes discovered in clusters below stones and under water in the neighbourhood of springs; and often seen in the bottom of ponds, marshes, and ditches, where water is collected, and the whole surface covered with ice. In this situation, we have frequently examined their sides and their nostrils and can venture to assert, that they did not respire in the same manner that they did when on land: for the moment that this animal is put under water, the palpitating motions of its sides and its nostrils are observed to cease; and Chaptal has seen them suspending respiration as it were at pleasure even when in air †.

While they move, however, and exhibit indications of active life, we would not say that air is excluded. In the roots of plants, in aquatic worms, in polypes, and in the placenta itself, the same organs seem to perform the double office of lungs and absorbents. When

* Encyclopedie Methodique.

under water, what are the functions of these organs in frogs and in toads? It is not disputed that in moist places they can live longest without food; and some phenomena which have been observed relating to this subject appeared to us not unworthy of attention. In the beginning of the summer 1793, while we were making a few experiments on the nervous influence with some metals, a frog was taken out of the water in the dusk of the evening, and put into a deep and wide-mouthed glass till next morning: but next morning a quantity of water was found in the glass, the animal was dead, its mouth full of foam, and the greater part of its body covered with froth. The following autumn a boy came with a couple of toads wrapt up in tow. Till we had leisure to make our experiments, they were allowed to remain as they were for three days in the corner of a room. When taken out, their colour was pale, their bodies much swelled, and a quantity of water collected between the skin and the muscles. When held in the hand with their head upwards, the water was evacuated downwards by the anus. It was one of these toads that afterwards died when confined in the glass without air. Its body was put into a solution of madder for two days; and when the skin and muscles were removed, the bones, which are still preserved, were found red. A live frog in the same solution, though allowed to breathe, expired in a few hours. In three days its bones became of the red colour, but not so deep as that of the toad's. Another frog died in the solution; but the bones, from age or some other cause, did not receive the colour of the madder. In all cases the skins were found red.

As we know not how far the great accommodating principle of nature may be extended, perhaps the absorbents opening externally may in these animals sometimes supply the place of the lungs, as the lungs supplied the place of the gills which they used when tadpoles, and as the gills had formerly supplied the place of a placenta, or the primary absorbents, through which they derived their nourishment in ovo.

Those stones which inclose animals are known to be such as have gradually assumed the solid form, and those animals which have been inclosed are known to be such as in other cases have been subjected to the torpid state: But this state has not been examined with all the attention which it deserves. From this state, Bonnaterre says, in his introduction to Ereptology*, that it is impossible to rouse the animal by the loudest noise, the rudest shock, or the deepest wound; the internal motion is just sufficient to preserve the system from that decomposition to which animal substances are exposed. It retains only the form of what it was. It appears neither to live nor to grow; and the whole mass, if what is exposed to the air be excepted, is not sensibly altered while the torpor continues. All the senses are shut up; all their functions are entirely suspended: digestion is no longer in the stomach; all respiration has apparently ceased; and it has been doubted whether or not this function be in some cases at all retained. When the genial warmth, however, returns,

in six, in eight, or in ten months, according to that variety of climates between the frigid poles and the tropics, the animal revives. But the question is, if the first circumstances in which the animal became torpid had been artificially or naturally continued, how long in this way might the different functions of life have been suspended; and how far are we warranted by the analogy of seeds and of eggs to lengthen this period of their existence, without supposing a decomposition or destruction of organs?

Experiments must tell what are the limits which nature has here prescribed to herself. New eggs, when covered with varnish, or placed under the exhausted receiver, are secured against the attacks of corruption. Bomare, in his Dictionary, has mentioned three, which, protected from air, were found fresh in the wall of a church after a period of 300 years (D).— And if it be true that a snake found in a block of marble died as soon as exposed to the air, or if the parts in contact with air be the only ones which in torpid animals appear to be changed, it would seem probable that a total exclusion of this varying and active element would tend more to the preservation of torpid animals, in certain instances, than a free admission, which, in those cases where all vital functions have ceased, is regularly found a principal agent in their dissolution.

M. Herissant of the French Academy was the first philosopher who, by means of experiment, thought of interrogating nature herself upon this subject. On the 21st of February 1771, he with great accuracy shut up three toads from the air, two of which were taken out alive on the 8th of April 1774. D'Aubenton says†, after a period of 18 months; but in this instance we depend more on the friend‡ of Fontana, who has mentioned the dates. The two toads were again inclosed, and Herissant died before there was a second inspection. D'Aubenton says, that when taken out their bodies were hard and shrivelled, and their whole moisture totally absorbed. A fourth toad that had been inclosed was heard to croak whenever the box in which it was confined happened to be shaken. Since that period the practice is common of confining snails in a sealed phial, where they exist in torpor for years.

These phenomena still excite wonder, but to wonder less, and examine more, would sooner procure us that information which we are wanting. In these observations concerning toads, have no circumstances been overlooked? Has it been determined whether they lived in the heart of stones, or, existing merely in a torpid state, had come alive when exposed to air? We have seen a toad that was dead for two days; its body was opened; its heart was seen motionless, but exposed to air in a few seconds it began to beat.— Considering the complex function of absorbents, we perhaps might conceive how a toad could live in the clefts of rocks, or the hearts of trees, where there is moisture; but has it yet been determined whether all stones in which toads have been found supplied them with moisture? We at least are certain that they did not

(D) See Bomare, under the article Œuf; and a fuller account of the same eggs in the *Dictionnaire de Merveilles de la Nature*, under Œuf.

Respira-
tion.

absorb the animal fluids, like the plaster used by the French academicians.

One of the toads was heard to croak after being inclosed. In making their experiments, has it, therefore, been thought a matter of indifference by the French philosophers, whether the animal was immersed alive in the full exercise of all its functions, or existing only in its torpid state? and with respect to this singular state, (might not the questions be fairly put), have its several kinds, have the causes which induce it, or those degrees to which it may be carried in different animals, been yet ascertained? Is not our knowledge of the torpid state at this moment principally the result of casual observation? Has it not been oftener than once supposed that the torpor of all animals is similar, or takes place to a similar degree? Have not torpid animals been therefore spoken of in general terms? and has it not been asserted that they retain a portion of heat and internal motion? though some have been found congealed in the ice, and many been dried to such a degree that they could be revived only by moisture.

57
Queries
respecting
this kind
of experi-
ments.

“That snakes and fishes, after being frozen, have still retained so much of life as when thawed to resume their vital functions, is a fact,” says Mr Hunter, “so well attested, that we are bound to believe it.” How came it, we would ask, that fishes which had been frozen by this truly ingenious physiologist never recovered? He recovered parts of different animals which had been frozen? Had the snakes and fishes of which he had heard been only partially congealed in the ice? or had the fishes which he selected for these experiments been properly chosen? or may all animals with equal fairness be made the subject of such experiments? and may all transitions from heat to cold, and from cold to heat, whether slow or rapid, if not in the extremes, be viewed as nearly of the same consequence? Are all seasons and conditions of body equally favourable to this state of torpor? and will these causes which induce torpor by operating externally in the months of autumn be able to continue it by the like action in the months of spring? We can answer, no.

58
Reabsorp-
tion of fat
in the tor-
pid state.

It has been said that animals subsist in their torpid state by the reabsorption of fat. Has it therefore been proved that all animals, not to say living bodies, are possessed of fat? or if they be, has it been demonstrated that they have a superfluous quantity to be reabsorbed? Has it been shown that their waste of fat is always occasioned by this reabsorption; or has this reabsorption in all cases been of that kind to counteract the effects of abstinence? If it has not been proved that all animals contain fat, and that this fat is reabsorbed in their torpid state, ought not the general assertion to be limited? Granting that in many respects it were true, have not philosophers been here amusing themselves with logic, where they could have been employed in making experiments? Have they not ventured to give us conclusions, where we had reason to expect facts? and on this account has not their conduct been somewhat similar to that of navigators who, sailing along the coast of Patagonia on one side, and observing

a few men of an uncommon stature, have from thence peopled the whole of the country with a race of giants? or rather to that of some calculators, who, from seeing a few parts of a continent, have ventured to give a map of the whole, to describe kingdoms that are yet unexplored; and by their skill in addition and subtraction to exhibit the figure, the extent, and proportion of lands unknown?

Leaving therefore the torpid state as one of those subjects with which we at present are little acquainted, and of which we therefore cannot speak with certainty in the general abstract language of science; it will naturally be asked, In what respect is air so necessary to all living bodies in their active state, and how it contributes to the regular performance of the different functions?

The ancients, who were led by the heat of the blood to suppose a vital spark in the heart, who had noticed the appearance of smoke in the breath, and who had observed that fire was extinguished when deprived of air, naturally inferred that the end of respiration was to support their imaginary flame, to ventilate the blood in the arteries and lungs, and to keep alive their vivifying spark. They were far, however, from being agreed as to the manner how this was effected. Some were of opinion that a certain principle of the air was absorbed, to which they gave the name of *the preserver of life* †, or the food of the spirit ‡; while others were persuaded that the air acted as a refrigerator, and was merely intended to moderate the fire, to assist in expelling the fuliginous vapour, and preserve the system in an equal temperature.

‡ Spiritus
alimen-
tum.

The moderns, who, after all their researches, have been unable to discover this vital spark of the ancients, are more puzzled to assign an adequate cause for the heat than for any cold which they discover. To account for this singular phenomenon, they have been ransacking nature for causes; and perceiving that putrescence, mixture, and friction, are in many instances accompanied with heat, have thence conjectured that they sometimes operate in producing the warmth of the living body. But these are theories which have been imported from the hot-bed, the laboratory, and mechanic's shop, and which have never yet been countenanced by physiological facts and observations. No one has been able to show that putrescence exists in a healthy state, except in the feces: no one has proved that any mixture which regularly occurs in the alimentary canal or vessels, generates heat; and though friction has been a favourable hypothesis, yet those circumstances, in which it evidently produces heat, have not been discovered in the living body; and it is not determined whether it be there a friction of the fluids, a friction of the solids, or a friction of the fluids and solids together.

Of animal heat, the most rational theory, we think, is one which properly belongs to the last century; it is confirmed by modern discoveries, and has ascribed this heat to respiration. Many had observed, that those animals which respire most have the warmest blood (E).

60
Opinion of
Verheyen.

Lower

(E) Quod autem animalia calidiora fortius respirent, non probat respirationem illis potius datum esse, ad sanguinis refrigerium, quam calorem illum intensum produci a validiori respiratiōe: imo posterius non tantum aequè, et magis probabile apparet: quia secundum omnium sententiam calido vivimus, frigido extinguimur.

Respiration. Lower demonstrated, that this blood received a new and a brighter colour in passing through the lungs (f). Verheyen and Borelli both proved, that the air lost something by coming in contact with that organ (g). Mayow showed, that this something which the air loses is contained in nitre (h). Experience taught the workers in nitre, that this something was absorbed from the air (i): and Verheyen remarked, that it is also absorbed by the lungs; and is probably that which maintains combustion; which qualifies the air for giving support to animal life, and imparts to the blood the vermilion colour (k).

61 Supported by a discovery of Dr Priestley s. How well the whole of this reasoning was founded, is proved by the late discoveries of Priestley and other chemists. There is now obtained, in a separate state, an aerial fluid, which maintains both life and combustion, and gives a vermilion colour to the blood. It is extracted in a very large quantity from nitre; is one of the component parts of the atmosphere, and the vital principle of that element; without which, in most animals, life is extinguished. From some phenomena which happen in combustion, it has been termed *principium foris*. It was called dephlogisticated air by Priestley the first discoverer; as the great acidifying cause in nature, the French nomenclature has given it the name of *oxygenous gas*; and, as one of the causes on which the existence both of fire and of life depends, it is named *empyreal* or *vital air*.

62 Respiration the cause of animal heat, and how this heat is produced.

Late discoveries have shown farther, how this air may in respiration produce heat. From the most accurate investigations, it appears, that caloric, or the principle of heat, is a distinct substance in nature; that it combines with different bodies in different degrees; that it is the cause of fluidity in all; and that, in proportion to that capacity which they have for it, and to that distance at which they are removed from the fluid state, the more or less caloric they con-

tain. Aeriform bodies being all therefore exceedingly fluid, it must be evident, that when they are fixed or condensed in the blood, and made to approach nearer solidity, a quantity of heat must be evolved. A part of this is very plainly evolved in the lungs where the air is absorbed, as appears by the breath; and a part evolved by the action of vessels, as appears from nearly an equal heat over the system, from the partial heat of a morbid part, and the sudden transition from heat to cold, and from cold to heat, over the surface, when the vessels are affected by either internal or external stimuli. When the heat, thus evolved by the gradual fixation of that body with which it was combined, has been successful in making its escape by the lungs and integuments, the blood returns in a dark and a sluggish stream by the veins, and mingles again with the animal fluid, which before gave it spring, activity, and life.

Of that oxygen which remains in the system, part is employed in forming different saline combinations and supplying the waste occasioned by that constant reabsorption; which, from many experiments that have been made with solutions of matter, is known to take place in the solid bones. The use of that oxygenous gas which returns with the breath, is best understood after knowing its affinities. Its basis oxygen, combining with hydrogen, which is the basis of inflammable air, forms water; and combining with carbone, the carbonic acid. It carries, therefore, back with the breath a part of the carbone produced by the slight combustion of the blood, and a quantity of hydrogen arising from the watery fluid decomposed.

But oxygenous gas does not alone enter the lungs. Of 100 parts of the atmosphere, but 28 are oxygenous gas $\frac{1}{100}$ is carbonic acid, and 72 are azotic gas (l). These last, though intended chiefly for other beings different from man, which are in immense numbers on the globe, but which, like him and the nobler animals are not form-

Ut proinde non videatur aliquid a natura datum esse, quo intenditur frigus vitæ contrarium. *Verheyen*, Tract. 2. cap. 7. de *Utu Respirationis*.

(f) Postquam circulatio sanguinis innotuit, diu creditum fuit sanguinem venosum colore illo coccineo rursus indui in ventriculis cordis, et præcipue ubi calor, quem judicabant istius coloris auctorem, est intensior: At negotium istud peragi in pulmonibus, nempe respirationis beneficio, evidenter ostendit cl. *Lowerus* experimentis. *Ibid.*

(g) Inquiramus quale sit istud aereum adeo nobis et multis animalibus necessarium. Ut ejus defectu vita extinguatur citissime. Vulgaris enim aer dici non potest, cum illum per meatus notabiliores sanguini immitti conveniret, sitque experientia certissimum, animalia respirantia non tantum aëre simpliciter; sed etiam recenti continuo indigere, unde concludendum est tantummodo aliquas particulas subtiliores ab aëre fecerni, et massæ sanguinis immisceri, quibus spoliatus ad ulteriorem respirationem sit idoneus.

(h) Et quidem verisimile est, inquit *Mayow*, particulas quasdam indolis nitrosalinx, easque valde subtiles, agiles, summeque fermentativas ab aëre pulmonum ministerio fecerni, inque cuoris massam transmitti. Adeo enim ad vitam quamcumque sal illuc aë cum necessarium est, ut ne plantæ quidem, in terra, ad quam aëris accessus precluditur vegetari possint; sin autem terra ista aëri exposita, sale hoc fecundante denuo impregnatur, ea demum plantis aliendis iterum idonea evadet.

(i) In aëre autem quid nitrosum contineri norunt ipsi vulgaris nitri confectores, qui terram aut laterum fragmenta ex quibus nitrum elixivare intendunt, aëri liberiori diu multumque exponunt; utque ab omnibus undique ea tangente ac persuente uberius impregnatur, sæpius ventunt, atque ita suorum sumptuum et laborum ampliorum messem mercedemque referunt.

(k) Insuper, si post confectionem nitri terra aut laterum fragmenta exponantur libero aëri, ea denuo post aliquod temporis spatium, quodam sale nitroso abundabunt. Est autem verisimile, aerem gratia ejusdem materiæ et vitæ nostræ continuationi et ignis accensione necessarium esse; præcipue cum rursus experientia doceat ruborem sanguinis e corpore educti, per additionem salis nitri intensum iri in eodem prius modo secuti, per respirationem in corpore vivente. *Ibid.*

(l) These are nearly the proportions.

Respiration.

ed to breathe the empyreal air, must notwithstanding be of some important and essential use to all living bodies. It has accordingly been found by experiment, that pure and unmixed oxygenous gas cannot be breathed for any very considerable time without danger; that some azote is contained in the blood, and has been extracted from the muscular fibre, when properly treated with the nitric acid. According to Berthollet, five of its parts with one of hydrogenic forms ammonia or volatile alkali; which dissolves the glandular tumours of the body, and prevents the coagulation of blood and the thickening of mucus which arise from acids (M). The azotic gas may therefore in part unite with hydrogenic, may prevent the coagulation of serum, the catarrhus formation of viscid mucus, and many combinations that oxygenic might form, injurious to the system. The carbonic acid, which is $\frac{1}{3}$ of carbone and $\frac{2}{3}$ of oxygenic, may also be necessary in regulating the effects of the other two. In aerated water, its uses are very generally known: it allays the pain of the urinary bladder when excited by calculus; it has been employed in the cure of wounds, and been thought useful in the pulmonary phthisis. It is generated in the lungs of those animals which respire oxygenic. In small proportions it favours the growth of the vegetable tribes. These tribes readily decompose it; and, with the addition of other prepared oxygenic from water, restore what is pure to the general mass of the vital fluid, that plants and animals might thus live by the mutual performance of kind offices.

We return again to animal heat. Every theory that pretends to account for animal heat, ought also to account for that singular equality of heat which the system preserves, or endeavours to preserve, in different temperatures. The above theory explains it simply in the following manner.

64
How an animal preserves its natural warmth in a cold temperature.

Venous blood, if exposed to the air, is known to absorb a portion of oxygenic, and assume that colour which it has in the pulmonary veins and aorta. Suppose an absorption of a similar kind taking place in the lungs, a fact which may be proved by decisive experiments; it is plain that the oxygenic by this absorption must recede from its gaseous or fluid state; that a quantity of heat must be therefore evolved, which, along with the heat of the reflux blood, is carried away by that vapour which issues from the lungs. In the course of circulation the oxygenic will naturally incline with hydrogenic to form water: it will tend likewise to the formation of many other compounds; and, as it enters into new states, and is further removed from gaseous fluidity, it must still be giving out a portion of heat. If the surrounding temperature be cold, this separation will be easily effected. The caloric will, in that case, be greatly absorbed from the interior surface of the lungs and exterior surface of the whole body. The oxygenic, meeting with the necessary temperature, will readily pass into new forms; and the venous blood returning to the lungs, will demand a supply which

will be either greater or less according as the cold, by favouring the escape of the caloric, and promoting new combinations with oxygenic, had removed it from the point of usual saturation. Respiration.

The gradual evolution of heat is a proof that the temperature must be sometimes reduced before the oxygenic can properly enter into all the usual combinations of the system. Suppose the body then to be placed within a hot circumambient atmosphere. This atmosphere, if warmer than the animal, will be more apt to part with heat than to receive it; and the oxygenic absorbed, being thus unable to dispose of its caloric, will be prevented from passing into those combinations and forms where heat is evolved. The venous blood will therefore conduct it back to the lungs, and make a demand for a new supply; but proportionally less according as the hot circumambient air, by preventing the escape of the caloric, and the usual facility of new combinations, has confined its removal to a smaller distance from the point of saturation.

In this last case the thing principally entitled to notice is a very curious effort of nature to resist the growing increase of heat. In the warm atmosphere, as during violent muscular exertion, the exhaling vapour is commonly discharged in a greater quantity from the surface of the body; and consequently the heat furnished with an excellent temporary conductor, that in some measure counteracts the dangerous effects from without.

After all, the reader is not to suppose that he here has received a general theory of respiration. All living bodies are not supported by the same kind of aerial food. Oxygenous gas has indeed been honoured with the flattering appellation of vital air; and nitrogenous gas been usually distinguished by that degrading epithet azotic; a word which signifies destructive of life. But though man, and all the warm-blooded animals that have yet been examined, may die in respiring the nitrogenous gas, this gas however, which constitutes more than two thirds of the whole atmosphere, may in general be called the vital air of the vegetable tribes, and of not a few of the orders of insects which thrive and live in it. For while man, and others which respire as he does, emit both the hydrogenic and carbone, and return the hydrogenic not sensibly diminished; most vegetables and many insects eagerly inhale them, and emit oxygenic as noxious or useless. These effects are the indications of a radical difference in constitution. Even the fibres of those living bodies which exhale oxygenic, will, after death, attract it so powerfully, as to decompose the nitric acid; but those bodies which inhale nitrogenic, have so very weak an affinity to oxygenic, and so strong a one to some of the bodies with which it is combined, that they can easily decompose water and carbonated air.

What fishes respire is not ascertained. Neither the change of the air, nor of the water which they occasion when in close vessels, have, so far as we know, been fully examined. Chaptal is assured, that, like other animals, they are sensible of the action of all gases. 67
Respiration of fishes and their temperature.

(M) Weak volatile alkali dissolves mucus, whose morbid viscosity Fourcroy has ascribed to a too great absorption of oxygenic.

Respiration. **68** **Temperature of plants.** **69** **How the natural heat of living bodies is to be estimated.** croy says, that they do not generate the carbonic acid; and that the air which Priestly and he found in the air vesicles of carp was nitrogene gas. Their thermometrical heat is so low, that in D'Arbenton's table they are reckoned among the cold-blooded animals.

various economical operations. What these are, in the different kinds of plants and animals, is not known. The bear, the hedge-hog, the dormouse, and the bat, may probably not digest when reduced to 73°, 70°, or 80°. The frog, however, will digest at 60° (N); and the birch before it arrives at 47° (O). It would seem that respiration, besides imparting aerial food, was intended to preserve and regulate these different degrees of heat. It raises the heat after a meal; it suffers it to fall in the time of sleep; it withdraws the supply when the atmosphere is warm, and increases it again when the atmosphere is cold. It should therefore be remembered, that heat merely is not the object which is solely aimed at in respiration. All living bodies have their congenial degrees of heat. The regulation of these is important: on the one side, it prevents the dissipation, on the other the coagulation, of their fluids; it preserves the living power of their organs; and, by a natural and proper temperature, assists their action in mixing, composing, in decomposing, and in variously preparing the different parts for secretion, excretion, absorption, reabsorption, and assimilation (P).

Respiration.
1. 60.
70
Certain degrees of heat natural to every species.

71
Regulated by respiration.

The temperature of plants is still lower. The heat of a tree which the very ingenious Hunter examined, though several degrees above that of the atmosphere when below the 56th division of Fahrenheit, was always several degrees below it when the weather was warm. When taken out, the sap was observed to freeze at 32°; while in the tree, it would not freeze below 47°. The very profuse perspiration of vegetables greatly moderates the heat in their surface; and as air which absorbs moisture expands, and becomes thereby specifically lighter, there is a regular current produced, and evaporation rapidly promoted by the dense air displacing the rarefied.

To adopt here a general language with respect to the heat which is developed in all living bodies, it is proportioned to the quantity of matter which is by means of the vital powers reduced to a state more nearly approaching solidity; to the kinds of the substances which are reduced, and to the degrees and kinds of the reduction.

In all living bodies there appear to be certain degrees of heat, peculiarly fitted for carrying on their

As various fixations of the vascular fluid are regularly taking place in the different parts of the living body, and as air is not the only fluid concerned, it should almost be unnecessary again to observe, that the whole of the heat is not evolved in the lungs, nor the whole that is evolved disengaged from air.

It

(N) See observations on certain parts of the animal economy by Mr Hunter. We allude here to his experiments and observations on animals, with respect to the power of producing heat.

(O) See Dr Walker's excellent Paper on the motion of the sap in trees, 1st volume *Philosophical Transactions, Edinburgh*.

(P) The ingenious Dr Crawford has published a theory of animal heat different from that which we have here presented to our readers. Assuming as a fact, that heat and phlogiston are two opposite principles in nature, he goes on as follows.

"Animal heat seems to depend upon a process similar to a chemical elective attraction. The air is received into the lungs containing a great quantity of absolute heat; the blood is returned from the extremities highly impregnated with phlogiston; the attraction of the air to that of the phlogiston is greater than that of the blood. This principle will therefore leave the blood to combine with the air: by the addition of the phlogiston, the air is obliged to deposit a part of its absolute heat; and, as the capacity of the blood is at the same moment increased by the separation of the phlogiston, it will instantly unite with that portion of heat which had been detached from the air.

"We learn from Dr Priestley's experiments with respect to respiration, that arterial blood has a strong attraction to phlogiston (become a vague word with different meanings in different authors). It will consequently, during the circulation, imbibe this principle from those parts which retain it with the least force, or from the putrescent parts of the system: and hence the venous blood, when it returns to the lungs, is found to be highly impregnated with phlogiston. By this impregnation its capacity for containing heat is diminished. In proportion, therefore, as the blood which had been dephlogistated by the process of respiration becomes again combined with phlogiston in the course of circulation, it will gradually give out that heat which it had received in the lungs, and diffuse it over the whole system.

"To account for the stability of animal heat, he observes, that as animals are continually absorbing heat from the air, if there were not a quantity of heat carried off equal to that which is absorbed, there would be an accumulation of it in the animal body. The evaporation from the surface, and the cooling power of the air are the great causes which prevent this accumulation: and these are alternately increased and diminished in such a manner as to produce an equal effect. When the cooling power of the air is diminished by the summer heats, the evaporation from the surface is increased: and when, on the contrary, the cooling power of the air is increased by the winter colds, the evaporation from the surface is proportionally diminished." See *Crawford on Animal Heat*, p. 73—84.

Besides, supposing that the principles of fire and inflammability are opposites in nature: this theory supposes that the blood, while in the lungs, gives out phlogiston and takes in heat; but that, during the remaining course of circulation, it gives out heat and takes in phlogiston: it supposes, that this phlogiston is collected from parts that retain it with little force, or from the putrescent parts of the system; it is not said where: it supposes

Respiration.

It may further be remarked, that the whole of the air does not enter by the lungs; much is contained in the liquid and solid parts of the food. It is extricated often in the process of digestion; and when the organs are vigorous and healthy, is made subservient to the general economy. If the organs, however, should happen to be languid, it loses their authority, which cannot be enforced; from being friendly, it soon becomes inimical to the system, and threatening danger accumulates, not only in the stomach and intestines, but in other cavities. It has been found in the cellular membrane; in certain vesicles formed for itself; in the uterus; in an abscess; and in gun-shot wounds: It has sometimes burst from the vagina with a sort of noise*. And in a nephritic complaint of a horse, we have observed it flowing in a stream from what the farriers denominate the *jsualb*.

* See observations on Diarrhea, by the late Mr Hunter. † Borelli de Motu Animalium, cap. 23. De Natatu, prop. 209. ‡ Chaptal's Elements of Chemistry, vol. i. § 5. chap. 2.

§ Anatomical Description of the Disease of Numbness, by the French Academy.

73 Respiration.

In some kinds of aquatic plants, in eggs, and in a variety of fishes, there are certain vesicles containing air, which seem to have certain necessary functions allotted them by nature. In the plants and in fishes they were once supposed to have been wholly intended for swimming (Q). It was remarked, that those fishes which remain constantly at the bottom of the water have no air vesicle; and that a fish whose vesicles was burst by means of the torricellian vacuum, though it lived for a whole month after in a pond, was never able to rise to the surface. The practice, however, which some fishes have of ascending at times to inhale air, and descending after their vesicle is filled; the communication which, in some fishes, this air vesicle has with the stomach; that power in the pigeon and some other birds of introducing air into the crop; and lastly, the air which is uniformly found in impregnated eggs—would tempt us to believe that these natural collections of air, with their other uses, may perform some essential service in nutrition.

Having explained the general intention of respiration, we are now to inquire, what are the kinds of respiratory organs, and in what manner their functions are performed? The preceding table has in some measure made us acquainted with the subject. Some animals breathe by a trachea and lungs; insects, by either stigmata or trachea, opening into air vessels; plants,

by air vessels and leaves; fishes, and numbers of the watery element, if they do not breathe, at least receive air by their gills; the fetus in ovo, the polypus tribe, and many more organized bodies, by the same organs which convey their food.

Respiration.

The absorbents appear to be the first and most general way by which living bodies are supplied with air: the mouths of these vessels are like small tubercles, scattered over the body of the insect while wrapt in its membrane. In the horse and the bird they are blood-vessels spreading on a membrane, and deriving nourishment from the uterus or egg, that had been itself nourished by absorbents: In a cow, they are vessels which, spreading on a membrane, terminate in glands; these glands being opposite to others which adhere to the uterus; and the membranous and uterine glands, when in contact, inclosing a third gland like a kernel. In man, they are vessels spreading on a membrane, and entering a large glandular body called the *placenta*. In the mouse and the hare, they are likewise vessels branching on a membrane, and entering a placenta: this placenta, when it appears to be fixed, receives large veins from the parent, and which may be either inflated or injected from the cavity of the uterus.

74 Absorbents.

Those which are properly respiratory organs, exercise not their function till circulation and nutrition are begun: though, if the observation of Garman be just, that the air may become a real food for the class of spiders, or if it be true that the larvae of ants as well as of several insects of prey, increase in bulk, and undergo their metamorphoses without any other nourishment than air, this law is not universal. It may, however, be doubted, whether some moisture be not absorbed. With regard to the ant, we have reason to suspect that the observations on which such a conclusion was founded have not been accurate.

75 Respiratory organs late in exercising their functions.

§ Chaptal's Elements of Chemistry, vol. iii. § 1, art. 5.

Not only are the respiratory organs thus late in exercising their functions; in many vegetables a great part of them is annually renewed and laid aside in the torpid state. In those insects which undergo the most remarkable kinds of transformation they suffer a change; and in all those animals which spend their earlier days in the water, and afterwards come to live in the air, they are altered in kind.

76 Sometimes renewed, sometimes changed for a different kind.

In

supposes that the blood, in passing through the lungs, receives heat only: that the whole of this heat is evolved in the lungs by precipitation; and is thence diffused over the system as from a centre or focus: in which case, we must also suppose that the lungs are the warmest part of the body; and that the heat of the other parts will be in proportion to their distance from the lungs, or the length of the vessels through which it has passed.

As for the stability of animal heat, this theory ascribes it entirely to foreign causes; to the different degrees of evaporation; or to the varying states of the air.

The singular meaning which this theory gives to the word *Phlogiston*, must strike every one who knows the etymology of that word. The celebrated Stahl found it in the Greek; and applied it naturally to signify pure elementary fire, or the most pure and simple inflammable principle in a state of combination. Mr Kirwan has since used it to express hydrogene: Dr Priestley has called the azotic phlogisticated air: and Dr Crawford, who seems to take phlogiston in the sense of Mr Kirwan, speaks likewise as if he understood it in the sense of Dr Priestley. Mr Kirwan's phlogisticated air, however, will not kindle without oxygen: Dr Priestley's will extinguish fire; and Dr Crawford's is directly opposed to that principle. These are not the ancient doctrines of Stahl: they are new ideas expressed in one of his antiquated words; the meaning of that great man is neglected. The sounds which he uttered, like the dead language of an old ritual, are among a few still in veneration.

(Q) Borelli has shown how, by contracting the air vesicle or allowing it to expand, the fish can rise, sink, or remain stationary in the water. *Borelli de Natatu*.

Respiration.

Respiration.

In all living bodies the proper function of one part of the respiratory organs is, to secrete from the water or air that particular aeriform fluid, which mingles with their juices, and which is necessary to life and nutrition. In many cases these organs are placed externally, and are always in contact with the air or water from which they secrete. In other cases they are lodged internally; and air or water are then alternately admitted and expelled by varieties of organs which serve as auxiliaries.

bouring parts of the plant secrete what is needed: for in plants and a certain number of insects, the functions of the lungs, the stomach, and the heart, are generally diffused. The several parts can respire, digest, and circulate fluids on their own account; and if they should chance to be severed from the whole, can live and grow, and propagate their kind.

77
Respiratory organs of plants;

The plants secrete their aeriform fluid from water and air. They receive air along with the liquids of their absorbents, which open on the roots, the trunk, and the branches, and upon the inferior surfaces of leaves; or, if nature has plunged these leaves under water, the absorbents open and imbibe their fluids on both sides. In many, however, the upper surface of the leaf is intended to inhale air. Bonnet observed, that when this surface was applied to the water the leaf died soon; but that when the lower surface was applied, it lived for months. It has also been remarked, that the upper surfaces of some leaves will repel water; and that the death of the leaf will ensue when its breathing pores are obstructed with oil*. We hence learn why aquatic plants rise up to the surface of the water and spread their leaves in the open air; and as it is proved by Ingenhousé and others, that the respiration of many leaves is assisted by light, we see a reason why plants growing in a dark room turn to the place where light is admitted; why the flowers and the leaves of many plants follow the diurnal course of the sun; why the branches of trees, which require much light, die when placed in a thick shade; why moonshine in autumn contributes so much to the ripening of grain; and why leaves and branches are arranged in such a manner as least to intercept that quantity of light which nature has allotted to the genius of each.

The air vessels are surrounded by those which contain a liquid during the whole time of the growth. They are the largest vessels of the wood, as distinguished from the bark; and in the leaves they may sometimes be seen even without the assistance of glasses. Their cavity is formed by certain fibres which wind spirally like a cork-screw. In the leaf they generally approach and recede like the filaments of nerves; but they never anastomose from one end of the plant to the other, except at the extremities; they resemble the pulmonary tubes of insects by their general disposition over the system, and the spiral rings of which they are composed (κ); they differ in this, that the pulmonary tubes are frequently observed to anastomose in their larger branches, as the ramifications of a vein or artery do in their smaller capillary twigs.

§ Grew's Anat. of Plants, B. 3. ch. 3. § 27—29. and B. 4. part 1. ch. 4. § 17 —19.

* Botanic Garden, note 37.

The air vessels in the body of plants are those vessels which contain juices but at certain times, and which during the greatest part of the season are filled with air †. This air is collected from the sap of the roots as it passes along the diametral insertions, and from those vessels which open upon the trunk and upon the leaves ‡. Like pulmonary tubes, which are seen branching through the bodies of insects, they perform an office similar to that of the tracheæ and bronchia; and are those general receptacles of air from which the neigh-

bouring parts of the plant secrete what is needed: for in plants and a certain number of insects, the functions of the lungs, the stomach, and the heart, are generally diffused. The several parts can respire, digest, and circulate fluids on their own account; and if they should chance to be severed from the whole, can live and grow, and propagate their kind.

The respiratory organs, which are similar either to the gills of fishes or the lungs of man, can hardly here claim a description, as their nature and forms are to generally known. There is one circumstance, however, in birds which arrests our attention: the cells of their bones, and the numerous vesicles of their soft parts which communicate with the lungs, have been deservedly a matter of surprise to most physiologists. In accounting for their use, the ingenious Hunter supposed that they lessened the specific gravity and assisted flying; that being the circumstance which he thought most peculiar to birds. Learning afterwards that they were in the ostrich and not in the bat, he supposed that they were appendages to the lungs. In amphibious animals, in the snake, viper, and many others, he observed, that "the lungs are continued down through the whole belly in form of two bags, of which the upper part only can perform the office of respiration with any degree of effect, the lower having comparatively but few air vessels (s)." In these animals, the use of such a conformation of the lungs was to him evident. "It is in consequence of this structure," said he, "that they require to breathe less frequently than others." From this reasoning he naturally

Of insects;

(κ) See the spiral rings in the pulmonary tubes of a bee, Plate XVII. fig. 10. Swammerdam's Book of Nature, or History of Insects.

(s) The same observations were long ago made by the immortal Harvey. After observing that both the transverse and longitudinal membranous diaphragms of birds contributed to respiration, he adds, "Et alia, ut nunc taceam. Avic præ cæteris animalibus non modo facillime respiciat, sed vocem etiam in cantu diversimode modulatur: cum tamen ejus pulmones lateribus et costis adeo affixi sunt, ut parum admodum dilatari, assurgere, et contrahi possint.

Quinetiam (quod tamèn a nemine hæcenus observatum memini) earum bronchia sive asperæ arteriæ fines in abd. meo perforantur. Aëremquæ inspiratum intra cavitatè sillarum membranaarum recidunt. Quemadmodum pisces et serpentes intra amplas vesiculas abdomine partas, eundem attrahunt et reserant, eoque facillius natant existimantur. Et ut ranæ ac bufonæ cum ætate vehementius respirant, aëris plus solito in vesiculas numerosissimas abfrahunt (unde earum tam ingenuè ut ovis quo eundem postea in conxatè ne liberè expirant. Ita in pennatis pulmones transius et via ad respirationem videntur quam hujus adequatum organum. De Generat. Animal. Exercit. 3.

Respira-
tion.

usually inferred, that the motion of flying might render the frequency of respiration inconvenient; and that a reservoir for air might therefore become singularly useful. The bat and the ostrich, however, are here as formidable objections as before. The bird respire frequently when at rest, and when it flies to our bosom from the hawk; that frequency seems to have been increased by what is a general and a common cause, an increased degree of muscular exertion. Had air cells been intended merely to prevent the effects of a rapid motion on respiration, we might expect to see them in greyhounds and a number of quadrupeds, much more readily than in some birds whose flights are neither rapid nor long.

This great physiologist was not aware that the circumstance most peculiar to birds was not their act of flying, but their feathers, which contain a large quantity of air, and which require a regular supply, whether they soar on the wings of the eagle, or remain on the ground, attending the ostrich (r).

Both in amphibious animals and birds, the air of the vesicles has passed the respiratory surface of the lungs. In the tracheæ of plants and the pulmonary tubes and vesicles of insects, it is only proceeding on its way to be respired. Would it be worth while to inquire whether vegetable substances, and those which are called corneous in animals, require a different preparation of air from what is the common preparation of lungs? whether hair grows best, or the cuticle thickest over soft parts that are cellular and spongy (v)? and whether the animals that bear horns have larger sinuses in the frontal bone of their cranium than others? From the general diffusion of air through the birds, and the situation of their vesicles beyond the lungs, it would appear that the pulmonary viscous in these animals does not respire or secrete air for the whole system; and we

I

are certain, that in plants and insects most parts respire the air for themselves, and that there is no particular part appointed to secrete air for the whole.

We here speak of respiratory organs as those which secrete an aeriform fluid from water and air; but our language probably had been more accurate had we called them the organs in which an aeriform fluid is absorbed by their liquid contents, as these flow by, either wholly or in part, in their course through the system. It was long denied that any absorption of the air took place from the pulmonary surface; and speculative reasoners had attempted to prove that no air could pass to the blood through the membranes of the lungs, because air had refused upon some occasions to pass through pieces of wet leather that had been exposed to it for that purpose. Borelli, however, endeavoured to show how air in the lungs might mingle with the blood, and how some always disappeared in respiration. There are few doubts now entertained on this subject. Venous blood enclosed in a bladder by the celebrated Priestley discovered such an attraction for oxygen, that it absorbed the aeriform fluid through all the coats of the resisting medium, exhibiting an instance and beautiful illustration of the chemical affinities which take place in this function.

The reader will observe, that the two words *respiratory organs* are here employed in what may be called rather a particular sense. The truth is, there are two kinds of respiratory organs, which, though sometimes included in the general expression, should always be considered as perfectly distinct. The first kind comprehends those in which the water and air is decomposed; the second, those by which these fluids are properly applied to the respiring surfaces of the former. We observe these last in the fluttering motion of the leaf itself, or in that tendril which turns the surface of the

gans.

(r) "The use of this retention (of the air in the vesicles of birds) is not well known to us, at least in respect of the upper pouches; so in regard of the lower ones. The use of this retention has been explained in the description of the OSTRICH: where it was shown that there is a probability that the air contained in the lower pouches serves to compress the viscera, and make them rise upwards. Some do think that this retention of air serves birds to render them lighter in flying, like as the bladder which is in fish helps them to swim. And this conjecture would have some foundation, if the air contained in the bladders of birds were as light in proportion to the air in which they fly, as the air contained in the bladders of fish is in proportion to the water in which they do swim. But to say something which hath at least a little more probability, waiting till we have a more certain knowledge of the truth and use of this retention of air, we consider that the birds generally rising very high, and even to the place where the air is a great deal lighter than it is near the earth, might be deprived of the principal advantages of respiration for want of an air whose weight might make on the heart and arteries the compression necessary to the distribution and circulation of the blood: If they had not the faculty of containing a long time a portion of air, which being rarefied by the heat which this retention produceth therein, might, by enlarging itself, supply the defect of the weight of which the air that they do breathe in the middle region is destitute. For if there be a great many birds which do never rise very high into the air, whose lungs have notwithstanding these bladders in which the air is retained; there are also a great many that have wings which they use not for flying. And it may be observed, that there are found some parts in animals which have not any use in certain species, and which are given to the whole genus, by reason that they have an important use in some of the species. It is thus that in several kinds of animals the males have teats like the females; that moles have eyes; ostriches and cassowars wings; and that land tortoises have a particular formation of the vessels of the heart which agrees only with water tortoises, as it is explained in the description of the TORTOISE." *The Anatomical Description of a Cassowary*, by the Royal Academy of Sciences at Paris. We can hardly answer for the justness of this reasoning, which maintains that the genus has useless parts merely in compliance to the species.

(v) Nails and hair grow after death, and a quantity of air is evolved in putrefaction.

Respiration.
82
Auxiliary organs of respiration,

the leaf to the sun. We see them producing these oscillatory motions in the branching gills of the *pulex arborescens*. When the breathing surface is within the body, we discover them again in the tracheæ of plants, whose cavity is formed by a spiral fibre that is seemingly intended for some kind of peristaltic motion. We detect them likewise in the pulmonary tubes, in the spiral rings, and in the abdominal movements of insects. We see them in fishes swallowing the water and propelling it onward through the fringes of the gills. In the frog, we note them by the motions of the pouch between the sternum and the lower jaw. After this animal is divided transversely behind the fore legs, this pouch continues to fill and to empty itself downwards by the trachea where the lungs were. When the whole integuments and some of the muscles between the jaw-bone and sternum are removed, we see how the pouch was dilated and contracted by a broad cartilage connected with the trachea, and attached by muscles to the inside of the sternum and the neighbouring parts. When the pouch is enlarged, the air rushes in through the two nostrils at that time expanded; and when it is contracting, the glottis starts up with an open mouth to the middle of the pouch, and the air is pressed down through the trachea to the lungs. This amusing sight will sometimes continue for a whole hour. In man and all the warm-blooded quadrupeds, the thorax or cavity where the lungs are placed is dilated and contracted by the diaphragm and muscles attached to the ribs. In the time of dilatation the glottis opens, as we see in birds: the air rushes in, supports the incumbent weight of the atmosphere, and enables the thorax to expand wider. The expanding powers having made at last their usual effort, their antagonists succeed, exert their force, and the air is expelled.

83
Assisted by the pressure of the atmosphere

In applying either the water or air to the breathing surface, all these auxiliary organs are assisted by the circumambient fluid which presses equally on all sides. When a Florentine flask is applied to the mouth, and all communication between the larynx and external air entirely cut off, it requires an effort to bring the air of the flask into the lungs. The weight of the atmosphere is therefore assisting in respiration; and the air, whether in the lungs or the thorax (x), must not be so dense as that which is without. When Verheyen perforated the thorax of a dog, and restored the equilibrium betwixt the external and internal air, the respiration of the lungs ceased, though for some time the alternate admission and expulsion of air was continued through canulas introduced into the wounds.

84
How this pressure raises the thorax.

It cannot surely be asked here, how the pressure of the atmosphere should be assisting in raising the thorax and thus seemingly counteract itself? The heat of the lungs expands the air as soon as it enters. The air rapidly absorbs moisture; and though not usually noticed by philosophers, yet the sudden expansion, which is always the consequence of that absorption, is a very general phenomenon in nature. By this heat, or by this absorption, the air would occasion greater dilatation, were it not for the lungs, which seek to collapse;

VOL. XIV.

the cartilages of the sternum, which seek to recoil; and the stretched-out muscles, which either spontaneously, or directed by the will, endeavour to contract and produce expiration.

Respiration.

Having seen how the air will rush in on the opening of the glottis, we may also conceive how the flattening of the glottis will resist the force of internal expansion, and support a weight laid upon the breast. The confined air will expand equally on all sides, and the pressure must be great before the space which falls to the glottis can exceed its own muscular force and the weight of the atmosphere. It is this diffused pressure of fluids that produces such striking wonders in hydraulics; and which explains how the droppings of the ureters should expand the bladder even to a palsy, and overcome the abdominal muscles.

85
How the expansion is continued.

To account for the action of these organs which serve as auxiliaries in respiration, there have been supposed an appetite for air which prompts as a stimulus; an influence of the will, though we breathe while asleep; and a natural instinct, which indeed may exist, but explains nothing. In specifying the several organs concerned, we have heard of an expansile power of the lungs, of a certain pressure of the phrenic nerve, of a muscular diaphragm, and of the action of oblique intercostals. But these explanations are from a limited view of the subject. The expressions used may indeed be general; but their meaning is particular, narrow, and confined; and their allusion is only to man, or perhaps to a few of the warm-blooded quadrupeds: for where are the intercostals of the frog? where is the muscular diaphragm of birds? where the pressure of their phrenic nerve? and where the expansile power of their lungs?

86
Opinions concerning the organs of respiration.

It is fortunate for man that these assisting respiratory organs are in some measure subject to his will. By this subjection he produces vocal sound when he pleases, divides it into parts, varies it by tones, forms it into words, and enjoys the distinguished and numerous advantages that may be derived from a spoken language.

87
What organs form articulate sounds.

SECT. II. Digestion.

As respiration succeeded the placenta in one of its offices by maintaining life, the function of digestion succeeds it in another by either continuing or supporting the growth of the living body. It depends on respiration for a portion of heat, and is that function by which the liquid and solid food undergoes its first preparation in the system.

88
Digestion.

Though gaseous fluids, including the principles of heat and light, may be proved to nourish and compose the substances of all living bodies, yet a part only can enter the system in a gaseous state. This part is changed by the lungs, or by those fluids which they contain. The organs of digestion, before they can act on aerial bodies, must have them reduced to some new form. For the food of vegetables, this form requires to be water, whose 100 parts are found to consist of 84½ of oxygen and 15½ of hydrogen. See WATER.

89
Gaseous fluids compose the substance of all living bodies, and two of the gases form WATER.

4 S When

(x) Supposing that there be any in the thorax.

Digestion.

When the gases have passed through both the watery and vegetable states, they, as juices or solids, become the food of a great many animals. These animals produce new changes, and by their preparation the gases become the food of others which are called carnivorous; and then the carnivorous and all living bodies, when the vivifying principle has ceased within them, and when they are hastening to a state of dissolution, are devoured by others who feed on corruption, are partly converted into water and gas, and become in their turn the food of the kinds on which they had fed.

As these effects of the digesting and assimilating powers are more surprising than any chemical process of art, it may not be unpleasing to take a more particular view of them. It has long been observed, that those animals which are not carnivorous feed upon plants; and, since the days of Van Helmont and Boyle, it has been suspected that plants live upon water and air. This suspicion has now been confirmed by numerous experiments. Plants have been raised from distilled water without earth, and, instead of requiring a vegetable mould, have spread their roots in moss, in paper, in cotton, in pieces of cloth, in pounded glass, and powder of quartz. From these facts, the ingenious Chaptal has been led to suppose that soils act but as so many sponges, affording water in different proportions, and in different ways; and that all that the plant wants from the soil is a firm support, a permission to extend its roots where it chooses, and that proportioned supply of humidity which will secure it against the alternatives of being inundated or dried up. To answer, however, these several conditions, he allows it to be necessary in many cases "to make a proper mixture of the primitive earths, as no one in particular possesses them. Siliceous and calcareous earths (he says) may be considered as hot and drying, the argillaceous as moist and cold, and the magnesian as possessing intermediate properties. Each, in particular, has its faults, which render it unfit for culture. Clay absorbs

water but does not communicate it; calcareous earth receives and gives it too quickly; but the properties of these earths are so happily opposed that they correct each other by mixture. Accordingly we find, that by adding lime to an argillaceous earth, this last is divided, and the drying property of the lime mitigated, at the same time that the stiffness of the clay is diminished. On these accounts it is that a single earth cannot constitute manure, and that the character of the earth intended to be meliorated ought to be studied before the choice of any addition is decided on. The best proportions of a fertile earth for corn are three eighths of clay, two eighths of sand, and three eighths of the fragments of hard stone.

The advantages of labour consist in dividing the earth, aerating it, destroying useless or noxious plants, and converting them into manure by facilitating their decomposition."

So far is vegetable mould from communicating any thing new to plants, that it rather owes its formation to them*, and if sea salt should at times be requisite to marine vegetations, it is to be remembered that salts, sulphur, and lime, are all products of organized bodies; that iron (v) itself has been discovered in plants and animals; and that even diamonds, quartz, crystals, spars, gypsum, &c. are found only in those earths that are partly composed of an impoverished vegetable residue, which provident nature seems to have reserved for the reproduction or reparation of the earthy and metallic substances of the globe; while the vegetable mould on these organic parts that remain are made to serve as nourishment for the growth of succeeding plants (z.)

If those earths in which plants are reared, and which contain no vegetable mould, should ever be sensibly diminished in weight, a circumstance, we believe, which seldom takes place if proper precaution be used to prevent it; yet if it should happen, it should not in that case be forgotten that gates are the general cements in nature; that they mix intimately with the hardest bodies; and that this sensible diminution of weight

(y) Whether iron exists formally in organized bodies, or is the result of decomposition, it derives its origin ultimately from gases. Blood gradually decomposed by putrefaction yielded not only more salts and lime, but much more iron than blood, suddenly decomposed by lime. Though the greater part of an animal or vegetable, therefore, be without such substances as salt, lime, iron; yet when decomposed its parts may recombine, and thus produce them. See *Surgical and Physical Essays*, by Mr John Abernethy,

(z) "Vegetables in their analysis present us with certain metals, such as iron, gold, and manganese. The iron forms near one-twelfth of the weight of the ashes of hard wood, such as oak. It may be extracted by the magnet. We read in the *Journaux de Physique* an observation, in which it is affirmed that it was found in metallic grains in fruits. Vegetables watered with distilled water afford it as well as others.

"Becher and Kunck I ascertained the presence of gold in plants. M. Sage was invited to repeat the processes by way of ascertaining the fact. He found gold in the ashes of vine twigs, and announced it to the public. After this chemist, most persons who have attended to this object have found gold, but in much less quantity than M. Sage announced. The most accurate analyses have shown no more than two grains, whereas M. Sage had spoken of several ounces in the quintal. The process for extracting gold from the ashes consists in fusing them with black flux and minium.

"Scheele obtained manganese in the analysis of vegetable ashes.

"Lime constantly enough forms seven-tenths of the fixed residue of vegetable incineration. Next to lime, alumine is the most abundant earth in vegetables, and next magnesia. Siliceous earth likewise exists, but less abundantly; the least common of all is the barytes. *Chaptal's Elements of Chemistry*, Part iv. § 3. art. 15.

See Salts, Sulphur, Iron, Lime, in *Elements of Chemistry*. See the *Matrix of Diamonds*; see *Chaptal*, vol. iii. Part 4. § 5. art. 3.

Digestion. weight may be owing entirely to some dissolution of the solid parts, and the consequent extrication of the gaseous fluids (A).

“ Before we had acquired a knowledge of the constituent principles of water,” resumes Chaptal, “ it was impossible to explain or even to conceive the growth of plants by this single aliment. In fact, if the water were an element, or indecomposable principle, it would afford nothing but water in entering into the nutrition of the plant, and the vegetable would of course exhibit that fluid only; but when we consider water as formed by the combination of the oxygenous and hydrogenous gases, it is easily understood that this compound is reduced to its principles, and that the hydrogenous gas becomes a principle of the vegetable, while the oxygen is thrown off by the vital forces. Accordingly we see the vegetable almost entirely formed of hydrogen. Oils, resins, and mucilage, consist of scarcely any thing but this substance; and we perceive the oxygenous gas escape by the pores where the action of light causes its disengagement.”

But though water constitute the aliment of plants, we must not suppose that it is the aliment of these alone: the leech and the tadpole* are nourished by water, and many animals have no other food. “ Rondelety cites a great number of examples of marine animals which cannot subsist but by means of water by the very constitution of their organs. He affirms, that he kept during three years a fish in a vessel constantly maintained full of very pure water. It grew to such a size, that at the end of that time the vessel could no longer con-

tain it. He relates this as a very common fact. We likewise observe the red fishes which are kept in glass vessels, are nourished, and grow, without any other assistance than that of water properly renewed †.”

The ingenious Borelli, who knew that plants and several animals subsisted wholly by water and air, was likewise of opinion that some animals lived upon sand. He could discover nothing but sand in the stomachs of many testaceous animals that live in the water, and particularly in the stomachs of the smaller kinds that live buried in the sand of the sea. He could not conceive what else could be the food of those small fishes or worms which penetrate the substance of the hardest rocks, and form excavations that always bear a proportion to their bulk. He had regularly found that the stomachs of swans which he had examined were full of sand; and, recollecting the pebbles in the gizzards of fowls, he was led to infer that these substances were somehow dissolved in a gastric juice, and served to nourish the harder parts, as the shells, the feathers, and the bones (B). These sentiments, on a slight view, might not be unnatural. From observing children of depraved appetites swallowing sand, ashes, and cinders; from having sometimes met with sand in the stomachs of wild ducks; from the usual traces of the earth-worm; and from the dissection of several toads dug up in a garden, in whose stomachs we could see nothing but a quantity of earth, with pieces of coal, stone, and of slate, that had accidentally happened to be mixed with it (C), we long entertained a similar opinion with this celebrated author: but on recollect-

“ In this account the fixed air was previously extracted from the limestones by acids, and the heat applied was much less than was necessary to extract all the air from the bodies employed.”

(B) A similar inference was made by Mr Burt upon opening the stomach of the pangolin of Hindostan. See PANGOLIN.

(C) The third ventricle had a strange body fastened to its interior membrane. This body was composed of a hard membrane, in which there was gravel inclosed. Gesner says the chamois is accustomed to swallow gravel to clear his tongue and throat from the phlegm, which is apt to cover them, and destroy the appetite. *Anat. Description of the Chamois or Gemp*, by the French Academy.

Digestion. ing that many substances which enter the stomach are not nutritious; considering the balls of hair and of feathers which the carnivorous animals return, and that quantity of faecal matter which is discharged by the intestines; having frequently experienced that a sense of fulness removes hunger, and observed persons as it were by instinct pressing on the empty stomach with their hand—we began to suspect that the swallowing of sand, and a number of other indigestible substances, might not be to nourish but to prevent some cravings of the stomach, and that these cravings were in part occasioned by a deficiency of the usual pressure which it receives from the neighbouring parts. In this opinion we were more confirmed, by hearing it was customary among some of the tribes of the north of Asia to repel or mitigate the attacks of hunger by placing a board over the region which is called epigastric, and compressing it gradually by means of cords as the stomach collapses; and by learning afterwards, on a further inquiry, that a similar practice, and from similar motives, was likewise common with some individuals in this country; who to alleviate the sensation of hunger, straiten the epigastric region with their handkerchief. This practice, however, being often impossible with the brute kind, instead of bringing the neighbouring parts to press on the stomach, they are obliged to distend the stomach, and to bring it to press on the neighbouring parts. Of the two ways of producing this pressure, the last is certainly the most natural. Senebier has supposed that distension of the stomach is the cause of the secretion of the gastric liquor; but how well or ill his opinion may be founded, daily experience permits not a doubt, that in order to satisfy the calls of hunger, the stomach requires not only to be nourished, but to be filled, or at least to have something like a sense of fulness; and this may probably be one reason for those balls which are found in the stomachs of the chamois, which likewise swallows sand, and in the stomachs of the cow, the sheep, and of the horse, “when they do pass away the winter in snowy mountains, where they can find no grass” (D).

97
The organs
of digestion
in the ve-
getable.

From this general view of the food, the natural transition is to those organs by which it is prepared. As all plants are fed on nothing grosser than liquids, we see the reason why they are all nourished by absorbents, and why, instead of one common alimentary canal, they are furnished with a number of capillary vessels, which by their action assist the living power in moving the fluids along the trunk, the branches, and the leaves.

Digestion. These fluids are observed to move between the different ligneous circles, and the more copiously as the wood is younger or the nearer the circles are to the bark. In the circles themselves, it has been remarked that the sap vessels, from being empty during a great part of the growing season, have been called air vessels; that they are formed of spiral fibres, adapted to some peristaltic motion (E): and it is plain, that by this structure they are well fitted to propel their contents, whether water or air, upwards or downwards, backwards or forwards, according to the different positions of the plant.

Besides the particular action of the vessels, a general concussion is received from the movement of the waters or winds, which serves as an exercise; a general dilatation is occasioned by both moisture and heat; and a general contraction by dryness and cold, which produce a motion something similar to that of the thorax †.

In the springing season the sap ascends through the empty vessels before the leaves begin to appear. When the vessels are filled through their whole extent, the buds swell, the leaves spread, and the flowers blow; the evaporation from the surface is increased; the sap is diminished by the absorption; the succiferous vessels now cease to bleed (F); and the roots being unable to supply the waste, the rains and the dews enter by the trunk, the branches, the leaves, and the petals of the flowers. When the evacuations are immoderately increased by excessive heat, or preternaturally obstructed by the plucking of the leaves, by too much humidity, or other causes which prevent perspiration, the plant soon either sickens or dies. The chyle, which is formed in the sap vessels, has generally something of a saccharine taste.

Considering the forms of animal food, we may naturally expect in the animal kingdom a greater variety of those organs employed in digestion. Most animals have indeed, like the vegetable, both inhaling and exhaling vessels, by which some of their fluids are absorbed, and evacuations regularly carried on. Except, however, in those animals which subsist by liquids, these vessels are of little importance in receiving food or ejecting what is faecal from the system. In these animals the absorbents terminate in a hollow viscus, which is called the alimentary canal, where the fluids undergo a preparatory change, and are partly reabsorbed for assimilation. In all others the food enters by a proboscis (G), or by an aperture which is called

mal.

(D) Bartholine, quoted by the French Academy, thought that these balls were composed of the hair which the cows lick from their skin, or of the wool which the sheep eat. But the horse does not lick himself, and many of these balls seem to be composed of ligneous fibres. The balls which are found in the chamois are called by Velselius *German lezoar*. See *Anat. Description of Chamois or Gems*, by the French Academy.

(E) “The superior part of the intestine, which contained about thirteen inches, had a very particular structure; for, instead of the ordinary circumvolutions of the intestines, the cavity of this was transversely interrupted with several separations, composed of the membranes of the intestine folded inwards. These separations were near half an inch distant from each other, and turned round like the shell of a snail or of a staircase with an open newel.” *Anat. Description of the Sea-fox*, *ibid*. These membranous folds running spirally, are not uncommon in the alimentary canals of animals.

(F) This happens in a great many plants.

(G) Every person may have an opportunity of seeing a proboscis in a number of those winged insects which extract juices from plants. It is very easily discernable in the butterfly. In this insect it is a fine moveable tube,

Digestion. the *mouth*: this mouth is properly the entrance of the alimentary duct. It is very generally furnished with a tongue (*n*), which is usually assisting in deglutition; and if the food be of that nature to require cutting, tearing, or grinding, it is likewise furnished with the proper instruments (*o*) for these operations. When the food is testaceous or some hard vegetable substance, and these instruments not in the mouth, something similar may generally be expected in a more remote part of the canal. The crab and the lobster have accordingly grinding teeth in their stomach, and granivorous fowls have a powerful gizzard lined with a thick corneous substance. It possesses the compressing force of the jaws; and small pebbles which the animals swallow serve it for teeth.

101
Food triturated in the mouth or stomach.

102
In what manner diluted.

103
In different animals.

Besides mere trituration or grinding, the solid food will often require to be mixed with some additional liquid (*κ*). In those carnivorous animals which chew, this liquid during the time of mastication flows into the mouth from certain glands placed in the neighbourhood. In some species of the ape kind a previous dilution takes place in two pouches situated on the sides of the lower jaw. In granivorous birds this dilution is very usually performed in a sac (*l*), which is a dilatation of the canal; and the food being macerated there by the glands or exhaling vessels, gradually passes down (*m*), as is needed, to be triturated and farther prepared in the stomach. In the ruminating kind the dilution is performed in a similar manner: but these having no muscular stomach fitted for grinding instead of descending the food is brought up again into the mouth, and is then after the proper mastication sent to the stomach. If the food require no mastication, it is sent directly that way at first: a circumstance which shows a curious discernment with respect to foods, and proves that their alimentary canal is subject to the action of voluntary muscles as far as the stomach. Some of those birds which have a diluting sac or ingluvies seem likewise to ruminate.

This in the parrot was observed by the gentlemen of the French academy. It has since been observed in rooks, macaws, cockatoos, and others; and Mr Hunter, to whom physiology is so much indebted, discovered, that the male and the female pigeon secrete in their ingluvies a certain liquor for feeding their young; and that most kinds of what have been thought ruminating birds do very often in expressing their fondness regurgitate their food. Yet both this and another species of regurgitation which is very common with those animals that swallow indigestible substances with their food, should be carefully distinguished from rumination.

Digestion.
104
Rumination of birds.

To the ruminating kinds the diluting sac is by no means peculiar. The porpoise has one, though it does not ruminate; and many of those animals which have none, as the rat, the hog, and the horse, have a part of the stomach covered with a cuticle, and which must therefore principally serve as a reservoir. The gullets of several fishes and serpents are sacs of this kind. It frequently happens that a part of their prey is projecting from the mouth, while another part fills up the gullet and gradually descends, to be reduced in the solvent below. So very dilatable are the stomachs and gullets of some animals, that serpents have been often seen to swallow whole animals which, prior in the gorging, were larger than themselves; and many polytypes, and even some of the louse kind will, by swallowing food, more than double their own bulk.

105
Part of the stomach serves as a reservoir.

Applying *stomach* as a general word to the different ventricles of the canal, we may here observe that every species of animals which ruminate have two stomachs, or at least two divisions in one; that some have three, as the gazella; and some four, as the cow, the dromedary, and the sheep: but it must not be supposed that the number of stomachs is any proof of a ruminating power. It was said already that the porpoise has two; the porcupine has three divisions in one; and the singular cassowary, although it be found to have four stomachs, does not rumi-

106
Number of stomachs.

tube, possessing a great variety of action. It serves for a hand, a mouth, and a gullet; and when not extended in search of food, it is coiled up in circular folds. The elephant has both a mouth and proboscis, and this proboscis is one of the most singular of living organs.

(*n*) The crocodile has no tongue; the ostrich, the seal, and some others have forked tongues; the cormorant has a double tongue; some, like the eagle, have a cartilaginous tongue; some, like the porcupine, have it toothed. We have found a bone in the tongue of a goose; the tongue of the caracoon, is a hollow trunk like a proboscis; the tongue of the frog is forked and long—it is rolled up in the mouth, and originates from the fore-part of the lower jaw. In some the tongue is the organ of taste; in others, the instrument for seizing their prey. In distinguishing foods most animals rely chiefly on smell.

(*o*) These instruments are corneous, bony, or calcareous; they are teeth or bills; their situation is the tongue, the jaws, the palate, or the stomach. Many teeth seem intended only for attack or defence, for seizing, killing, or retaining the prey. This is remarkable in the fangs of serpents, and in the large tusks of the elephant, the barbiroussa, and some other animals, where they have some resemblance to horns, and project from the mouth. The philodotus and ant-eater have no teeth; the larvæ of insects have generally two, which are placed externally, and cut like a forceps.

(*κ*) There are many persons whose tongues and mouths are naturally dry, and when they swallow a piece of bread must call for water or some other moistener. This complaint is even sometimes general in a family, and is propagated like an hereditary evil through its different branches. Cockatoos and parrots have likewise dry mouths.

(*l*) The bustard has no sac of this kind; but the œsophagus is remarkable for the largeness of its glands.

(*m*) In the ostrich the œsophagus passes down and returns, and the crop opens from below upwards into the gizzard.

Digestion. ruminant; nor, although granivorous, is any one of the four a gizzard.

107
Reservoirs
of water in
the ibex and camel.

Somewhat different from these expansions which we have been mentioning as existing in the first part of the alimentary canal, is a sort of pouch (N) which hangs from the neck and the lower mandible of several birds, and which, like the two pouches of apes, may be used either to macerate the food or to carry provisions from a distance to their young. The pelican, a native of warm countries, employs this pouch sometimes to carry a quantity of water; and another native of the same countries, we mean the dromedary, was observed to have at the top of the second of the four ventricles a number of square holes, which being the orifices of as many cavities between the membranes which compose the ventricle, reminded the gentlemen of the French academy of those large reservoirs of water which Pliny mentions to be in camels; and for which, according to his story, their guides have opened them sometimes in cases of extreme thirst.

108
The gastric
juice.

We come now to one of the principal agents in digestion. Independent of the fluids which mingle with the food in the mouth, the gullet, or macerating sac, there is one denominated the *gastric juice*, and which, either by itself or along with others from the aliments or system, acts in some measure as a solvent. It is secreted from large glands at the entrance of the gizzard, from vessels or glands in the coats of the stomach, and perhaps most plentifully near the pylorus: it powerfully resists the putrefactive fermentation; it coagulates milk and the white of an egg; it dissolves food even when inclosed in metallic tubes; and when life ceases, it acts frequently on the very stomach from which it was secreted. Its taste, its colour, and its solvent powers, are different in different classes of animals. It seems to be modified according to the age, the health, the habit, and the different aliments on which they live. The sick and the child are incapable of digesting the food that is proper for a healthy man. The hawk kind, after loathing bread and throwing it up without any change, can be gradually brought to take it for food; and Gassendi has mentioned a certain lamb which, being fed on bread, cheese, and on flesh, refused afterwards to taste grass*. But what is most surprising in the gastric juice is, that it spares all living bodies, as those worms which exist in the stomach, and the stomach itself while it is alive; and it differs otherwise from a chemical solvent, in that it has an assimilating power, and reduces all substances, whether animal or vegetable, on which it acts, to a certain fluid of determinate properties, which is called *chyle*.

*Borelli de
Nutritioe
Animal.
prop. 194.

109
The bile
and pan-
creatic
juice.

Besides the gastric, the food again, after passing through the stomach, is mingled with a greenish saponeous liquor, which is called *bile*, and which flows either immediately from the liver or from a vesicle into which it had regurgitated as into a blind gut; at the same time nearly it is mingled with another resembling the saliva from the pancreas or sweet-bread; a gland or glands whose place is supplied in a great ma-

ny fishes by a number of vermicular appendages to the stomach. **Digestion.**

In short, from one extremity of the alimentary canal to the other, fluids are perpetually flowing into its cavity from glands, vessels, or organic pores; and the membranes constantly secreting a mucus to protect themselves from the acrimony of their contents. This acrimony must often be considerable near to that end of the canal where the faeces are discharged; for as the first part of the canal has generally one or more dilatations which are called *stomachs*, and secretes at least one fluid which is strongly antiseptic, so the last part has generally appendages which are called *cæca*, where the food always remains for some time, and where, from the quantity of animal matter that happens to be mixed with it, it becomes putrescent. The office of the cæca is sometimes supplied by the largeness and convolutions of the colon (O); to which gut the ileum cannot, when it enters laterally, so easily communicate its peristaltic motion. As the stomachs were the receptacles of the food when it entered, the cæca are receptacles of the fecal matter before it be discharged. They are of various forms and capacities; they are often larger than the stomach itself; are often composed of proportionally thin and transparent membranes; and from their contents have often a colour somewhat resembling that of the gall-bladder. Their number is different in different animals. Some have but one. The birds which have them have generally two; the bustard has three; and Swammerdam has dissected insects which had four. As some stomachs have a number of folds which hang pendulous within their cavity, and increase their surface, so have often the cæca as well as some portions of the canal. The cæcum of both the rabbit and the hare is curiously formed. It is large and beautiful; it is rolled up like a cornu ammonis; it has the like outward appearance; and a fold running spirally is observed within. The animals which live on vegetable food have usually the greatest length of the canal, and the greatest number of stomachs and of cæca: yet the cassowar, which has no gizzard, has no cæcum; and the polype, which is said to be all stomach, is properly speaking rather all cæcum.

110
Other
juices.

111
The cæca
of the ali-
mentary
canal.

To see more fully the process of digestion, we must not overlook that general and organic action which takes place through the whole alimentary canal. The power of mastication exerted in the mouth is obvious to all. But the force of some stomachs has till very lately been known to few; we allude here to that of the muscular or gizzard kind: for Abbé Spallanzani has divided stomachs into three sorts; the muscular, the membranous, and intermediate. The immortal Borelli, who was probably the first that tried the force of the muscular stomachs by throwing into them nuts of silberds, hollow spheres of glass, hollow cubes of lead, small pyramids of wood, and several other very hard substances, supposed that the power exerted by the stomach of the Indian cock (P) was equal to 1350 pounds.

112
Action of
the ali-
mentary
canal.

Strength of
muscular
stomachs
first esti-
mated by
Borelli.

(N) A pouch of this kind is observed in the common rook.

(O) The bear, whose intestines are 40 feet long, has nothing resembling a colon or a cæcum.

(P) The original is *gallus Indicus*, which in the writings of Longalus, Gesner, and Aldrovandus, means a bird

Digestion. pounds weight. The force of an intermediate stomach cannot be so great, and that of a membranous one must be still less. Each seems to have more of the solvent as it has less of the muscular power. The most membranous are assisted by the action of the neighbouring parts, and expel their contents as readily as the strongest. The muscular fort is either wholly or principally confined to certain kinds of birds and of fishes, as nature has meant that the grain or the shells which they use as food should first be triturated before it be subjected to the gastric juice. This comminution takes place in their stomach, because it is plain that had bones or muscles, fully equal to all these effects, been placed in the head, the form of the animal must have been altered, or that equilibrium which it preserves in those fluid elements through which it moves been completely overturned.

114
Motions of the alimentary canal.

As to the movements of the alimentary canal, the direction of hairs found in the stomachs, and the balls of hair which are thrown up, would appear to indicate a circular motion. The intestinal part has a motion similar to that of a worm, and is called the *vermicular* or *peristaltic*. Here every portion retains its own motion, although it be separated from the rest by ligatures. The stomach of the polype, the gullets of the ruminating kinds, and the cæca, have this motion in different directions at different times; and that observed in the alimentary canal of a louse is, when view-

ed through a microscope in the time of action, amazingly rapid: the stimulating causes employed are the food, the different liquors with which it is mixed, the air, the nerves where they exist, and a portion of heat. Some degree of heat is necessary to every process of digestion both in the animal and vegetable kingdom: what that degree is depends on the nature of the living body; and is various according to its age, its health, its employment, and habits. The ingenious Hunter has mentioned the digestive and generative heats; and those gardeners who are versant in the operations of hot-houses, have on their thermometers the swelling, flowering, and the ripening heats, with a great many others for the several plants which they mean to raise.

Among the other causes of digestion some authors have ranked fermentation: and it must be allowed, that something similar to the putrefactive fermentation takes place in the cæca and the lower extremity of the intestine, and that the vinous and acetous fermentations but too frequently occur in our stomach when that viscus is morbidly affected (c).

Much of the history of living bodies relates to the different degrees of heat, the varieties of soil, and the kinds of food concerned in digestion. The plants grow where the soil and the heat are congenial to their nature; and those which admit of the greatest variety with respect to soil, and the largest range on the

bird different from the *coq d' Inde* or Turkey cock. Johnston has called it *gallus Perlicus*. See *The Anatomical Description of two Indian cocks* by the French Academy. *Gallina Indica* is Ainsworth's Latin for the Guinea hen. See *Borelli de Nutrit. Animal. Prop.* 189, 190, 191.

(c) "It may be admitted as an axiom (says Mr Hunter), that two processes cannot go on at the same time in the same part of any substance; therefore neither vegetable nor animal substances can undergo their spontaneous changes while digestion is going on in them; a process superior in power to that of fermentation. But if the digestive power is not perfect, then the vinous and acetous fermentation will take place in the vegetable and the putrefactive in the food of those animals which live wholly on flesh. The gastric juice therefore preserves vegetables from running into fermentation and animal substances from putrefaction; not from any antiseptic quality in the juice, but by making them go through another process, prevents the spontaneous change from taking place.

"In most stomachs there is an acid, even although the animal has lived upon meat for many weeks: this, however, is not always the case; therefore we must suppose it is only formed occasionally. Whether the stomach has a power of immediately secreting this acid, or first secretes a sugar which afterwards becomes acid, is not easily ascertained: but we should be inclined to suppose from analogy the last to be the case; for animals in health seem to have the power of secreting sugar, as I find in the milk, and sometimes in the urine from disease. The acid prevails sometimes to so great a degree as to become a disease, attended with very disagreeable symptoms; the stomach converting all substances which have a tendency to become acid into that form: the sugar of vegetables, and even sometimes vinous spirits turning directly into acid.

"To ascertain whether there is an acid naturally in the stomach, it will be proper to examine the contents before the birth when the digestive organs are perfect, and when no acid can have been produced by disease or any thing that has been swallowed. In the sink calf, near the full time, there is acid found in the stomach, although the contents have the same coagulating powers with those of animals who have suckled.

"Spallanzani gives the opinion of authors respecting digestion; and so anxious is he to combat the idea of its being fermentation, that he will hardly allow that fermentation ever takes place in the stomach. That fermentation can go on in the stomach, there is no doubt. It is often found that milk, vegetables of all kinds, wine, and whatever has sugar in its composition, become much sooner sour in some stomachs than they would if left to undergo a spontaneous change out of the body; and even spirits in certain stomachs almost immediately degenerate into a very strong acid. All oily substances, particularly butter, very soon become rancid after being taken into the stomach; and this rancidity is the effect of the first process of the fermentation of oil. Mr Sieffert has been able to restore rancid oils to their original sweetness, by adding to them their due quantity of fixed air; the loss of which I consider as the first process in this fermentation, similar to what happens in the fermentation of animal and vegetable substances." *Observations on Digestion by Mr Hunter.*

Digestion.
118
One intention of the locomotive power in living bodies to procure food.

119
Exerted by plants.

120
Farther observations on the locomotive power.

the scale of heat, are the faintest dispersed over the globe. As every soil has usually some regular supply of moisture, the plants that can live upon that supply extend their roots under the surface where their liquid food is the least exposed to evaporation, and meeting there with the constant nourishment which they require, they remain in that situation for life (R). If their trunks be so feeble as to need a support, they creep on the ground, they climb the face of a neighbouring rock, or cling to the body of some of the statelier children of the forest. Their range for food is extremely limited: it is chiefly confined to the small space which happens to be occupied by their roots and branches; yet if any uncommon exertion be necessary, the branches will bend, and the leaves turn to drink of the water that is passing by. If the roots be laid bare they will again plunge into the earth; if a stone or a ditch be thrown in the way, they will move round or will dip downwards, and spread into the soil on the other side: if there they arrive at one that is unfriendly they will not enter; but if a favourite earth should be near, though not in their direction, they will twist about, advance as they grow, and at last meet it. In all these cases the prop, the water, and soil, must be necessary; they must also be within a very small distance, otherwise the plants cannot perceive them, or will fail in their languid attempts to approach them.

It may be considered as a general fact, that wherever food is liberally supplied for a whole lifetime in one place, the creatures which use it have seldom much locomotive power, or much inclination to exercise it in a long continued and progressive line. The curious insect is therefore observed to deposit its offspring in those places where the prospect of genial warmth and of plenty seem to preclude the future necessity of wandering or research; and when this offspring is about to pass into a new state, and the organs foretel that a change or perhaps a variety of food will soon be required, the appearance either of wings or of legs do likewise foreshow that the power of locomotion is to be increased. Even nobler animals in their fetal state, where they live upon one species of food, and where that is afforded in regular plenty do spread out their roots, adhere to their soil, and become as stationary as the plant itself; and even when that supply is withdrawn, and they are expelled, yet if the state into which they emerge be helpless and feeble, if their organs of digestion have a weak solvent or masticating power, particularly adapted to some easily assimilated food, and if that food be presented either by their parent or nature without their exertion, their power of locomotion is not great, nor is it exercised in wandering afar. It is when the organs of digestion are

strong, and the appetite inclines to variety of aliment, and they are disposed and feel themselves able to wander in search of it; and that then they may be ready to move at intervals from place to place, when the enemy comes or the spirit prompts them, nature has directed them to solid food, and has given them a large alimentary canal with stomachs, with convolutions, and cæca, where they may lay up provisions for a journey; but afraid to entrust them with too much freedom, lest in their excursions they might wander from the places where subsistence is found, there are two appetites, hunger and thirst, which never fail in a state of health to remind them of their duty.

This variety of food, and the manner in which it is affected by climate are the cause of the many and singular migrations from spot to spot, from country to country, and from sea to sea: they are the cause of a state of torpor in the hedgehog and the bear, and they partly explain the provident foresight of the ant and of the bee. Animals of great locomotive power, in order to provide for themselves and their offspring, remove to a distant country or climate when they see the signs of approaching famine. Those of less locomotive power, and who are incapable of migrating far, as if warned by heaven, lay up a store for the scarcity to come; or should their food be of that kind as not to be easily preserved for a season, they require no secret warning to hoard it at the time when it fails, their system becomes susceptible of torpor, and they are enabled to sleep through the storm of trouble and of want. The source of this want is in most instances to be traced to the nature of the plant and insect. The plant which has little heat of its own depends on the sun or some other agent for one of the great causes of digestion. When this agent refuses the necessary heat, the plant must decline; its leaves, its juices, and its fruits must fail. The insect tribe, which had no other food, or which like the plant could not maintain their vivifying warmth, must likewise submit to the same fate. The various animals which live on either the one or the other, according to their several dispositions and characters, retire to their stores, to their dens of torpor, or migrate to a country to which they are led by unseen guides to share in its abundance. Of these last the rail (s) and the swallow are the only two which are sometimes arrested, and which, with the bear, the hedgehog, and the toad, are obliged to remain in the dwellings of torpor till the genial season of warmth and of plenty.

SECT. III. Absorption.

WHEN the food has undergone the first preparation, which is called *digestion*, and the chyle (τ) is formed in the

(R) Many of the fat plants live chiefly by the absorption of moisture from the air; and many sea-plants float through the ocean, and having plenty of food wherever they go, they send out no roots in order to search for it.

(S) All the birds on the lakes of Siberia are said by Professor Gmelin to retreat southward on the commencement of frost, except the rail, which sleeps buried in the snow. Account of Siberia quoted by Dr Darwin in his *The Loves of the Plants*.

(T) the chyle of different living bodies has not yet been analysed; in man it is generally a whitish fluid resembling milk, and yielding water, oil, sugar, and a coagulable lymph.

Absorption the alimentary canal or sap-vessels, it is thence taken up by means of absorption for the use of the system. From the vessels it passes into the whole cellular tissue, composed of vesicles, and closely interwoven with all the vascular part of the plant. From the vesicles or articles of the cellular tissue it enters the vasta propria and glands, which contain and prepare the fluids and secretions peculiar to the species.

123 In animals. In the animal economy it was always supposed that the chyle was absorbed by the ramifications of the red veins spreading on the gut, till the 1622, when Afellius an Italian discovered the lacteals (v) running on the mesentery of a living dog, and printed his account of them in 1627. As he had not traced their course very far, he naturally thought that they went to the liver, which was then imagined to be the organ of sanguification. This opinion, with respect to the place where they entered the veins, continued to be general till 1651, when Pecquet in France published his account of the thoracic duct (x). With great candour this author acknowledged, that he had been led to make the discovery by observing a whitish fluid mixed with the blood in the right auricle of the heart of a dog, which kind of animal it had been customary to dissect alive since the time of Afellius. "This practice of opening living animals furnished likewise occasions (says Dr Hunter) of discovering the lymphatics. This good fortune fell to the lot of Rudbec first, a young Swedish anatomist, and then to Thomas Bartholine (y) a Danish anatomist, who was the first who appeared in print upon the lymphatics. His book came out in 1653, that is, two years after that of Pecquet; and

124 The lacteals discovered in 1622.

125 Thoracic duct discovered in 1651.

126 Lymphatics discovered before 1653.

then it was evident that they had been seen before by Dr Highmore and others, who had mistaken them for lacteals; but (adds Dr Hunter) none of the anatomists of those times could make out the origin of the lymphatics, and none of the physiologists could give a satisfactory account of their use (z). The first known that Giffon, who wrote in 1654, has ascribed to these vessels the office of carrying the lubricating lymph from the several cavities back into the blood; and that Frederic Hoffman has expressed the doctrine of their being absorbents very explicitly.

It was on the 19th of June 1664 that Swammerdam discovered the valves of these vessels; and Ruyfch, who had seen them, perhaps very nearly about that time, first gave an account of them in a small treatise which he published at the Hague in 1665.

The best mode of demonstrating the lymphatics we probably owe to the celebrated Nuck, who, as a specimen of that complete system of Lymphography which he meant to publish (a), printed in 1691 his adenography, or description of the glands. In this treatise he not only tells us how he brought them into view, but in his plates represents many of them as filled with his new mercurial injections; a happy invention, which perhaps was suggested by remarking the extreme subtility of mercury when employed in the cure of venereal infection.

A method by which he inflated these vessels led him to suppose that they took their origin from veins or arteries, either immediately or through the intervention of some follicles (b.) The celebrity of his name procured credit to this mistake; and notwithstanding

Injected with mercury before 1691.

(v) We learn from Galen, that the lacteals in kids had long before been seen by Erasistratus, who called them *arteries*.

(x) This duct had been seen before by Eustachius. See *Eustach. de Vena sine pari*.

(y) The discoveries of Rudbec and Bartholine were made in the years 1651 and 1652, about which time Jolyffe an Englishman saw also the lymphatics.

(z) Drs Hunter and Monro claim the merit of having found out the true use of the lymphatics. The former says that he taught it in his lectures so early as 1746, and appeals to his pupils for the truth of the assertion. The latter seems to have made the discovery in 1753; and in 1755 published an account of it in a thesis *De Testibus in variis Animalibus*. Before the printing of this thesis, Dr Black told him that the same opinions concerning the valvular lymphatics had been long entertained by Dr Hunter. In 1756 Dr Monro attended Dr Hunter's lectures in London; heard the whole doctrine of the lymphatics very fully explained; and in 1757 reprinted his opinion at Berlin without taking notice of Dr Hunter's, who charges him with plagiarism; and the charge is retorted by Dr Monro.

(A) Lymphographia, quod essertur specimen, ubi lectori non ingratum percepero ad alias transiturus tum partes, non minus quam hæ, lymphaticis ductibus superbientes. *Prefatio ad Adenographiam*.

Nuck had traced lymphatics on the exterior parts of the head and neck, on the membrane of the lungs, on the spaces between the ribs, in the loins, on the diaphragm, on the heart, the spleen, on the liver, the gall-bladder, on the stomach, on the mesentery, on the tunica albuginea of the testes, in the feet, and in the hands. Ita (continues he), ut multiplici experientia et variis partium præparationibus eo usque pervenerim ut *integrum lymphaticorum systemæ* capite ad calcem mihi composuerim, ejus delineationem libenter tecum communicabo, ubi partium nonnullarum hæcenus nondum satis examinarum, Lymphographiam absolverimus. *Anton. Nuck de Inventis novis Epistola Anatomica ad D. D. B. G. Mod. Doct.*

(B) Quidam nervos constituunt vasorum lymphaticorum principia; alii glandulas minores; alii membranas; nec desiciant qui a tendinosa musculorum parte eadem deducunt. Sed multis aliorum sententiis, dicam modo; varia me hanc circa speculationem inolitum fuisse, variis experimentis (irrito licet ordinario conatu) varia tentasse, casuque tandem nonnulla detexisse quæ lucem, hic adierre possunt.

Ante triennium, mun dando leni vitulino intentus, omnique sanguine, aquæ tepidæ ope, jam citò, copiosum in arteriam splenicam infudi aërem, et, spiritu fortius adacto, non tantum plurimas exiguis in superficie lienis vidi elevari vesiculas, sed ex iisdem vesiculis vasa prodire lymphatica, flatu etiam turgida et lienem perrepantia vidi, et quo diutius arteria fuit inflata, eo majorem notavi vasorum numerum, ita ut, hac arte per in-

Absorption the founder opinion of Glisson, of Hoffman, and some others, the old notion that the veins performed the office of absorbents came so far down as the great names of Haller and of Meckel. The arguments, however, by which it was supported are shown now, and particularly by those of the Hunter in school, to have been injections that were not skilful, observations that were not accurate, and conclusions that were not logical; while the boasted assertion that birds and fishes were without lacteals and without lymphatics, has been disproved by the fortunate discoveries of Mr Hewson and Dr Monro. Excepting, therefore, in the penis and placenta, and in those animals whose veins may be injected from the gravid uterus, the lymphatics seem to perform the whole business of absorption. They contain a fluid that is coagulable like the lymph of the blood, and are called valvular to distinguish them from the arteries that do not admit the red globules. They derive their origin from the cellular membrane, from the different cavities, and from the surface. Some authors say that they have seen them in the brain (c), and these Mascagni has ventured even to describe in prints. That some indeed may exist in the brain, has not been denied; but to believe that they have been found, and to trust assertions which are not countenanced by the observations of skilful anatomists, requires a faith which for our part we do not pretend to. Both they and the lacteals derive their name from the colour of the fluids which they contain. They both empty themselves into the veins; but most of the lymphatics in the human subject, and all the lacteals, first unite in the thoracic duct, which near the heart leads into the course of the circulation.

SECT. IV. Circulation.

AFTER part of the food is converted into chyle, and this chyle absorbed by the lacteals, and brought into the course of the circulation, it remains to be distri-

buted to all the different parts of the system. On this account, Hippocrates speaks of the usual and constant motion of the blood †, of the veins and arteries as the fountains of human nature, as the rivers that water the whole body, and which if they be dried up man dies §. He says that the blood vessels are for this reason everywhere dispersed through the whole body; that they give spirits, moisture, and motion; that they all spring from one; and that this one has no beginning and no end, for where there is a circle there is no beginning (D). In such language was the prince of physicians accustomed to express his vague ideas of a circulation; for so far was he from having acquired accurate conceptions on this subject, that when he saw the motions of the heart, he believed that the auricles were two bellowses to draw in air, and to ventilate the blood.

When after his time anatomy came to be more studied, the notions of the ancients respecting the blood were better defined; and, however chimerical they may seem to us, they were partly derived from dissection and experiment. On opening dead bodies, they found that the arteries were almost empty (E), and that very nearly the whole of the blood was collected in the veins, and in the right auricle and ventricle of the heart. They therefore concluded that the right ventricle was a sort of laboratory; that it attracted the blood from the Cavæ; by some operation rendered it fit for the purpose of nutrition, and then returned it by the way that it came. From the almost empty state of the arteries, they were led to suppose that the right ventricle prepared air, and that this air was conveyed by the arteries to temper the heat of the several parts to which the branches of the veins were distributed.

To this last notion entertained by Erasistratus, Galen added an important discovery. By certain experiments, he proved that the arteries contained blood as well as the veins. But this discovery was the occasion

fiſtum vaſis lymphaticis vulnus aer immiſſus membrana linealis fere tota lymphaticis duſtibus obſeſſa fuerit viſa.

Ab eo tempore conjicere cæpi vaſorum lymphaticorum principia ab arteriarum ſurculis emanare, idque aliquando intermedia veſicula, aliquando deſiciente veſicula, immediate ab ipſa arteria venave. *Athenographia curioſa*, cap. 4.

(c) Sed rogare videris, utrum in cerebro etiam vaſa occurrant lymphatica? Quamvis ex recentioribus, nonnulli in eorum deſcriptione ſatis liberales, eadem concedant et facile admittant: Verum, quod paſſim obſervo, ſyſtemata in proprio cerebro formant et viſcera ex ſuo placito componunt: ad experimenta enim provocati nihil egregii præſtare valent. Nunquam hæc in parte, ut ingenuè loquar, hæcenus Scopum attingere potui. Interim non negandum cenſeo aliquando cerebri lymphatica in una aut altera parte fuiſſe viſa; et non ita pridem, anatomicus quidam mihi amiſſimus, inter alia inventa, hæc nobiſcum, communicat. "Vidi, inquit, lymphaticum in cerebro Bovino, quod examine tuo (ut originem ſcias et inſertionem) erit digniſſimum. Non longe a glandula pineali, a qua ramos forte habet, incumbit plexui choroideo, ad infundibuli latera ſeſe extendens." Ante biennium duſtum lymphaticum ex piſci glandula eodem modo ut aliis glandulis, exeuntem vidi. Ita ut quidem certifiſſimum, et cerebrum ſuos habere rivulos aquoſos, ſed nondum diſtincte, in lucem protractos. *Epiſt. Anat.*

(D) *Hippocrat de Venis*. "Plato, in his *Timæus*, ſpeaks of the heart as a watch-tower completely fortified, as the knot of the veins, and the fountain from whence the blood ariſes, and briskly circulates through all the members. The blood he calls the paſture of the fleſh; and adds, that for the ſake of nouriſhing the remotest parts, the gods have opened the body into a number of rivulets like a garden well ſtocked with plenty of canals, that the veins might by this means receive their ſupply of moiſture from the heart as the common ſource, and convey it through all the ſluices of the body." The reſt of the paſſage cited by Longinus is as full of nonſenſe as it well can hold: and indeed Longinus ſeems chiefly to have admired it for ſomething which had ſtruck him as divine and unparalleled in its tropes, as making the head a citadel, the neck an iſthmus, the vertebræ hinges, and the fleſh a rampart. See *Longinus on the Sublime*, § 32.

Circulation. of some embarrassment. How was the blood to get from the right to the left ventricle? To solve the difficulty in which his new discovery had involved him, he supposed that the branches of the veins and arteries anastomosed (F); that when the blood was carried to the lungs by the pulmonary vein, it was partly prevented by the valves from returning; that therefore during the contraction of the thorax it passed through the small anastomosing branches to the pulmonary vein, and was thence conveyed along with the air to the left ventricle to flow in the aorta (G). This opinion, so agreeable to fact, unfortunately afterwards gave place to another that was the result of mere speculation — This notion was, that the left ventricle received air by the pulmonary vein, and that all its blood was derived through pores in the septum of the heart.

135 How Galen supposed the blood to pass between the right and left ventricle of the heart.

136 Another opinion, supposed to be Galen's, refuted by Vesalius.

137 Vesalius roused the attention of anatomists to discover the true passage of the blood between the ventricles.

138 The passage discovered, and Galen's opinion revived, by Michael Servetus and others.

between their ligatures and the extremities, and not between the ligature and the heart. From these observations, he necessarily inferred that the veins and arteries anastomosed; and having also contemplated the nature of all the valves which were then known, and which had been known since the day of Galen, he ventured to assert that the blood could not return by the arteries to the left ventricle. One should imagine that numbers of conclusions he must have discovered the true circulation; but he did not. Being a zealous peripatetic, he thought himself bound to maintain with Aristotle that the blood flowed, like the tiles of Empiric, backwards and forwards in the same channel; and therefore supposed that it flowed from the arteries into the veins in the time of sleep, and from the veins back into the arteries in the time of waking. The greater circulation, so far as we can learn, was not even dreamed of by this writer. A farther step was yet to be made towards its discovery: and this was reserved for another professor of the Paduan school.

In 1574, Hieronymus Fabricius ab Aquapendente, while he was seeking for a cause to explain the various swellings of some veins which had arisen from friction and ligature, he took his great joy and astonishment discovered their valves in one of his dissections: and here again the true theory of circulation seemed almost unavoidable. Yet whoever reads the small treatise *De Venarum Officiis*, first printed by Fabricius in 1603, will soon perceive that he was as far from entertaining a just notion of the circulation as his predecessors. Notwithstanding all that he saw, he still was of opinion that the blood flowed from the heart to the extremities even in the veins. He thought that the valves were intended by nature only to check and moderate its force. He calls them an instance of admirable wisdom, and mistakes his own awkward conjecture for one of the designs of infinite intelligence. In another respect it must be confessed that he bore no inconsiderable share in promoting the discovery of the circulation (1). By writing on the valves, the formation of the fœtus, and the chick in ovo, he directed the attention of his pupil Harvey to those subjects where it was likely that the motion of the blood would frequently occur.

140 Had discovered itself upon Fabricius ab Aquapendente.

Harvey was born at Folkston in Kent in 1578, completed his studies at the University of Cambridge, went to Padua, and was there admitted to the degree of doctor, with unusual marks of approbation, in 1602. He examined the valves with more accuracy than Harvey.

141 Covered and fully demonstrated by his pupil Harvey.

+ T 2

(F) Intecto est mutua anastomosis atque osculorum apertio arteriis simul cum venis. *De Usu*, part 6. cap. 10.

(G) It was the opinion of Galen, that the motion of the lungs and the pulse of the arteries was to cool the blood, and to expel the fuliginous vapour. That he had just ideas of the lesser circulation through the lungs, and of the true nature of the valves, is evident from the passages cited by Harvey, *De Motu Cordis*, Exercit. 1. cap. 7.

(H) The words in which he mentions this discovery are these: "Non per parietem cordis, uti vulgo creditur, sed magno artificio a dextro cordis ventriculo, longo per pulmones ductu agitatur sanguis subtilis." Being born at Villa Nuova, in the kingdom of Arragon, he sometimes called himself Michael Villanovanus, or simply Villanovanus. In the title of all his books he takes the name of *Rever*, which is formed from Servetus, by throwing out the *de* and transposing the five letters that remain. The book in which his discovery was mentioned was printed clandestinely, and intitled *Christianity Restored*. Being first imprisoned at Vienna in Dauphiny, and afterwards allured to Geneva by the treachery of his correspondent and confidant John Calvin, he was, by a servant of that reformer's, accused of blasphemy, and condemned to the flames in 1553.

(I) Almost the whole merit of his discovery is due to the Paduan school, of which Cæsalpinus as well as Columbus was once a professor.

Circulation.

than his master Fabricius; and explained their use in a treatise which he published some time after. It is uncertain when he first conceived his celebrated doctrine of the circulation; but about the 1616 he taught it in his lectures, and printed it in 1628. He was the first author who spoke consistently of the motion of the blood, and who, unbiassed by the doctrine of the ancients, drew rational conclusions from his experiments and observations. His books present us with many indications of a great mind, acute discernment, unwearied application, original remark, bold inquiry, and a clear, forcible, and manly reasoning (κ); and every one who considers the surprise which his doctrine occasioned among the anatomists of those days, the strong opposition that it met with from some, and those numerous and powerful prejudices which it had to encounter from the sanction of time and of great names, must allow it was new, and that the author has from its importance a title to rank in the first class of eminent discoverers ancient or modern.

142
The merit of Harvey in this discovery.143
How the blood is circulated.

His discovery showed, that in most animals the blood circulates in arteries and veins, and through the medium of one, two, or of more hearts: that in arteries it moves from the trunk to the branches; and that, meeting there with the branches of veins, it returns in a languid stream to the heart; that the heart communicates a new impulse; that it drives it on to the trunk of the arteries; and that the arteries, by the thickness of their coats, exerting a force, do push it onwards again into the veins.

In every part of this circulating course, there are valves situated where it is necessary; they are meant to prevent the return of the blood; they are at the beginning of the great arteries, and are found in different places of the veins where their feeble action requires to be assisted.

The veins, before they enter the heart, generally expand into a thin muscular sac, which is called the *auricle*. It receives the blood while the heart is contracting; and when the heart admits of dilatation, contracts itself, and throws the blood into the ventricle.

We have here called the ventricle a heart; though what is usually meant by the heart be a ventricle and auricle; or sometimes a ventricle and two auricles, where the veins approach in different directions, and, without bending to meet one another, expand at two different places. Two hearts are sometimes united, so as in appearance to form but one.

144
In different animals.

From our having mentioned more than one heart, it will be supposed that the modes of circulation are various. In some animals the heart throws its blood

to the remotest parts of the system (λ); in other animals it throws its blood only into the respiratory organs: from these organs it is collected by the branches of veins; and these branches, uniting in a trunk, convey it to an artery, which renews the impulse, and acts as a heart. In a third set of animals, the blood from the respiratory organs is carried by the veins to another heart; and this second heart, united in the same capsule with the first distributes the blood by the channel of its arteries to the several parts. In the human fœtus, and the fœtus of those animals which have two hearts, a part of the blood, without taking the passage through the lungs, proceeds directly from auricle to auricle. In amphibious animals, the auricular passage continues open during their life, and is employed, when the breathing ceases, under the water. In many insects, a number of hearts, or expansions which answer the purpose of hearts, are placed at intervals on the circulating course; and each renews the impulse of the former, where the momentum of the blood fails. In the *Sepia Loligo* the two separate parts of the gills are each supplied by a heart of its own: the blood from both is collected into one; which, by two arteries opening at two different parts, send it at once to the opposite extremities. In numbers of animals, the heart, like the stomach, is in the extremity opposite to the head.

After the discovery of the circulation, the most interesting object with anatomists was to demonstrate it in a clear, satisfactory, and easy manner. Harvey, to show it with every advantage that he could think of, was obliged to open animals alive: but whether the animals were dead or alive, the larger branches of the veins and arteries were only to be seen, and even these but in certain cases, when they happened occasionally to be full of blood. That admirable method, which is now observed in demonstrating the course of the circulation, we owe to the great anatomists of Holland who flourished in the last century.

About 1664, Regnier de Graaf invented the syringe, which is now used; and, accompanied with a print, published an account of it in 1669. His injection was usually a thin fluid of a blue green or some other colour; his injection transfused through the vessels, allowed them to collapse by its general diffusion, and broke out through the first opening that happened in its way. A fluid which hardened after being injected, and which preserved the vessels distended, was a happier contrivance. This at first was either melted tallow or wax, of a colour suiting the taste of the anatomist.

So early as the year 1667, the celebrated Swammerdam injected the vessels running on the uterus with ceraceous matter; and, jealous

Of Swammerdam.

(κ) Dr Hunter says, that "none of his writings show him to have been a man of uncommon abilities. It were easy to quote (he says) many passages which bring him nearly to a level with the rest of mankind. He lived almost 30 years after Astruc published the lasterals, yet to the last seemed most inclined to think that no such vessels existed. Thirty hours at any time should have been sufficient to remove all his doubts; but this subject taken up in self-defence (continues the Doctor) grows unpleasant." Dr Hunter was here thinking of his own discovery when brought in comparison with that of Harvey's. When this comparison was less immediately in view, he says that "Dr Harvey, as appears by his writings, was certainly a first rate genius for sagacity and application; and his name is deservedly immortal on account of the many observations and improvements he made in anatomy and physiology." *Dr Hunter's First Introductory Lecture.*

(λ) We never exclude the action of the arteries.

Circulation. jealous left another should claim the merit of such an invention, he transmitted preparations, accompanied with plates, and with a full account of his method, to the Royal Society of London in 1672. Soon after, his friend Ruyfch acquired such skill in the art of injecting, that he has not been surpassed by any since his time. He discovered vessels in many parts where they were not supposed to have had an existence; and, contrary to the opinion of the great Malpighi, he showed that even many of the glands were entirely vascular; and that what had been supposed excretory ducts, deriving their origin from some follicle, were but terminations of arteries continued; yet even Ruyfch could not exhibit in all cases the course of the vessels so well as we do now. Another discovery was yet to be made for demonstrating their small capillary branches running through a part. This was reserved for the very ingenious Dr Nicholls of London; who invented the method of corroding the fleshy parts with a menstruum, and leaving the wax, as it was moulded by the vessels, entire.

148
Of Ruyfch.

149
Of Dr Nicholls.

From these researches, which evince circulation to be a function so general among animals, some are disposed to think it takes place in all living bodies. But notwithstanding the fashionable language of circulating fluids, of veins, arteries, and even of valves in the vegetable structure; yet nothing performing the office of a heart, and nothing that seems to conduct fluids in a circular course, has been found in plants. In the vegetable kingdom, the chyle is distributed to all the parts from the numerous vessels which convey the sap; and these vessels, being fitted by their structure to carry the sap either downwards or upwards, from the branches to the roots, or from roots to the branches; is the reason why plants inverted in the ground will send forth roots from the place of their branches, and send forth branches from the place of their roots. Even a similar distribution of the chyle takes place in some animals. In the human testis, in the fasciola hepatica of sheep, and in most polypes, the chyle, without a circulating system, is conveyed directly to the different part: from the alimentary canal. The taste for circulation may at

150
Circulation not universal in living bodies.

151
None in plants nor in some animals.

last subside. Till the business of absorption from the intestines was, of late, fully secured to the lacteals, we were wont to have also learned disquisitions upon a circular motion of the bile. The joint which it took was not very clearly; but it was found: it went with the feces down the intestines, and returned with the blood in the mesenteric veins.

Besides the circulation, another circumstance respecting the blood, which sometimes has engaged the thoughts of physiologists, is the colour which it has in most animals. The late Mr Hewson was of opinion, that the lymphatics, with the spleen (m) and the thymus, contributed greatly to the formation of the red globules. He was seemingly led to entertain this opinion from that attention to the lymphatics which made him ascribe much to their power, and from seeing red particles in the absorbents which rise from the splenic and the thymic gland. His reasoning, however, though very ingenious, is not conclusive. The celebrated Nuck, who had often observed a reddish fluid in the lymphatics, assures us, without any hypothesis, that such an appearance was always preternatural; and was either occasioned by a scarcity of lymph, or by some irregular and too much accelerated motion of the blood (n).

It is well known that the blood receives its vermilion colour in passing through the lungs; that animals with lungs have the blood redder than those which are seemingly without that organ; and that the colour, as well as the heat, is in proportion to the extent and perfection of the lungs. It has also been observed, that oxygenous gas is absorbed in respiration; and been proved by experiment, that the red globules of the blood, and the red only, contain iron. It thence would appear, that the colour is owing to iron calcined by the pure air, and reduced to the state of a red oxid. From this manner of conceiving the phenomena, says Chaptal, we may perceive why animal substances are so advantageous in assisting and facilitating the red dye (o).

A great variety of experiments have shown how much the colour and consistence of the blood is altered by

154
Respiration changes the colour of the blood.

(m) Before we can expect to arrive at a proper knowledge of the spleen, we have first to examine its form, its proportion, its situation, its numbers, and its different circumstances in different animals; and as yet this has been done only in a few cases. The gentlemen of the French Academy found, that in the demoiselle it was like the liver, in the bustard like the kidney of a quadruped, in the cham is round and flat, in the lynx narrow and long, in some animals proportionally large, in others proportionally small; that in the gazelle it was joined immediately to the stomach, without a vas breve; that in the castor, again, it was attached to the left side of the stomach by eight veins and arteries, and as many vasa brevia; that in the otter it was fastened to the epiploon, in the Canada stag to the great ventricle; and they found that in the prairie and sea-fox it was double. Since their time Dr Monro has observed two large spleens, one attached to the small and the other to the large curvature of the stomach of the squalus squatina or angel-fish, whose blood contains few red particles; and the same eminent physiologist found in a sturgeon no fewer than seven, one of the size of a dried horse-bean, and the rest about the bulk of a dried garden pea.

(n) Interim non dissiteor vasa illa lymphatica lympham subinde vehere rubicundo colore tingam, lotura canis ad inflar se habentem. Hoc autem nunquam contingit in statu naturali, verum post nimium et irregularem sanguinis motum. Vel in quibus humittum (ob defectum alimenti) deficit, qua occasione plerique humores vitiantur, et colore preternaturali tinguntur. Quid mirum itaque hinc in calibus et lympham reddi sanguineam. *Adnographia*, cap. 5.

(o) *Chaptal's Chemistry on the Properties of the Blood.* The physiologists of last century accounted for the red colour in another way. Rubedo sanguinis (says Verheyen) pro magna parte procedere videtur ab alimentorum particulis salinis ac sulphureis seu oleosis exaltatis. Cujus non leve indicium est, quod lixivium ex cineribus vulgari modo paratum notabiliter rubeat, in quo, præter aquam, vix aliud quam sal et sulphur reperibile est:—et lac

Nutrition.
155
Action of the vessels changes the colour and qualities of the blood.

By the mere action of the vessels; and this discovery has enabled us to conjecture with more certainty than we did formerly, why in infant and phlegmatic persons the blood is paler, in the choleric more yellow, and in the sanguine of vermilion red. It explains likewise, in some measure, why the blood varies in the same individual, not only with regard to the state of health, but likewise at the same instant; and why the blood which circulates through the veins has not the same intensity of colour, nor the same consistence, as that of the arteries; and why the blood which flows through the organs of the breast differs from that which passes languidly through the viscera or the lower belly. This power of the vessels over the blood will bring us also to the true cause why the vessels vary in the density of their coats and in their diameters; why they are sometimes convoluted in a gland; why they sometimes deposit their contents in a flicle; why they are sometimes of a spiral form; why the branches strike off at various angles; why they are variously anastomosed; why they sometimes carry the blood with dispatch and sometimes slowly through a tube and windings. By those means their action is varied, and the blood prepared in numerous ways to answer the ends of nutrition and secretion.

SECT. V. Nutrition.

NUTRITION is the function which assimilates the food in the several parts, and which finishes the process already begun in the stomach, in the lungs, and the vascular systems. In perfect animals some of the stages of this process are distinctly marked. The chyle, which has some resemblance to milk, is the work of the alimentary canal: it undergoes some new changes by the action of the lacteals and of their gland, when they exist. In the course of circulation it passes along the respiratory organs, and is mixed with oxygen or some other gas: by this mixture, the consequent heat, and the action of the vessels, it is turned into blood. The blood, when examined, spontaneously separates into three parts; an albuminous part or a serum, a coagulable lymph (P), and red globules. The two first are analogous to the white parts of an egg, by which the chick in ovo is nourished; the globules have some resemblance to the yolk, which serves afterwards as food to the chick in the more advanced period of life. The three parts contain each a variety of principles which are originally composed of gases: these principles, conveyed through vessels of various forms, of various diameters, and with various degrees of motion and of heat, and all along

varying as they pass, arrive at last on the confines of the parts which are wrapt up in a cellular tissue or some other membrane. The tissue or membrane gives a new change; the parts nourished perform the office of secreting organs; and as the action of the vessels is varied according to the place to which they are tending and the parts which they enter, we partly see the manner in which bone, muscle, cartilage, and nerve, are all secreted from a common mass.

In worms and polypes, the function of nutrition is after digestion carried on almost entirely by the cellular tissue; and in plants by a tissue cellular and vesicular. In all living bodies the cellular tissue besides giving a form to the parts, and besides preventing friction and cohesion, certainly performs some important office. Many have thought it the organ of nutrition; and it surely is one of the organs employed in assisting to assimilate the nutritious fluid. But it should be remembered, that all the parts of the living body are assimilating organs; that each part assimilates for itself; and that the stomach, the respiratory organs, the vessels, and nerves where they exist, are assistant to the whole and to one another.

It is singular how any should have imagined that the nerves are peculiarly the organs of nutrition, or that growth should be owing to the addition of some organic and vivifying particles pre-existing in the food. These physiologists have not demonstrated the existence of nerves in all living bodies; and these organic and vivifying particles have as yet been discovered but in their fancy. Dr Monro has descended to prove, that the limb of a frog can live and be nourished, and its wounds heal, without any nerves: and Mr Hunter has given many curious instances of a living and nutritious power in the blood.

In plants and animals, the assimilating power has always certain limits prescribed to it: its influence is very generally confined to the sort of food congenial to the species: and its strength is varied according to circumstances; as the age, the habits, and the state of health. These which are young assimilate faster than those which are old; and one species, which may partly be owing to the nature of their food, will assimilate much faster than another. Certain worms that feed on animal and vegetable substances will, in 24 hours after their escape from the egg, become not only double their former size, but will weigh, according to Redi, from 155 to 210 times more than before. Most oils are of very difficult assimilation; and those which are essential will often resist the long continued and the varied action of the living organs; will mingle with

(P) Senac was the first who discovered this lymph.

Secretion. with the parts, and, undecomposed, communicate their flavour.

162
Assimila-
ting power
of flame.

An assimilating power is not peculiar to living bodies; it is observed in ferments and contagion, and is so obvious with respect to flame which is neither living nor organized, that whole nations who have seen it feeding on inflammable substances, have been disposed to think it was animated, to call it the principle of life itself, and to pay it a kind of religious homage as the proper emblem of that Being by whom the whole universe is upheld.

In living bodies nutrition is only a species of secretion.

SECT. VI. *Secretion.*

Is a function in which a part is separated from the whole, and generally with some change of its qualities. In the case of nutrition it was observed, that all parts secrete for themselves; and that some few, as the lungs, the stomach, the vessels, and the nerves, officiate besides for the general use of the whole system.

163
Every
living body
in a state of
constant
waste and
repair.

If all the ingesta were to remain and to be assimilated, the body would go on continually increasing. But living bodies are constantly in a state of waste and repair. In most animals part of the ingesta is carried off by evacuation, without having entered the mouths of the absorbents; part, which enters the absorbents and veins, is thrown off by exhaling arteries or the urinary passage: and experiments with madder prove that the lymphatics, besides originating from all the cavities and carrying back the lubricating fluids, do enter the substance of the hardest bones, and convey particles that had been assimilated back into the blood.

164
An office
not gene-
rally ascri-
bed to the
absorbents.

This office has not been generally ascribed to the absorbents; nor has it been very generally supposed that the blood receives the excrementitious matters of the system, and that one intention of the circulation was either to return them for re-assimilation or to discharge them by exhaling vessels or by the kidneys. Decayed parts, however, are discovered in the feces evacuated by the intestines; in the clouds, the sediment, and colour of the urine, and by the smell of the perspirable matter. The two last, on certain occasions, and for some time, have often supplied the place of one another; and all the three, the feces, the urine and perspirable matter, we have reason to believe are remarkably distinguished by two kinds of odour; the one peculiar to the whole species, the other peculiar to the individual. By the perspirable matter which adheres to the ground, and of which the odour is diffused by moisture, the dog not only distin-

odour.

guishes a man from any other animal, but is able to trace his master through a crowd.

Secretion

The natural evacuations of plants, and of some few animals which feed by absorbents, are all by perspiration or exhaling vessels. The urine in quadrupeds is before emission collected in a vesicle, and thence carried off by the genital organ. In birds, and in a number of fishes, the ureters empty themselves into the rectum, and their contents are evacuated along with the feces.

166
Evacua-
tions of
plants by
exhaling
vessels.

Besides being used to denote the function, the word secretion is sometimes employed for the matters secreted. In this sense there are various secretions. Beside the feces, the urine, and the sweat, and the vapour from the lungs, which are excrementitious, there are secretions which answer useful purposes in the system. Of these the most important and general are the bile, the saliva, the gastric juice, and the pancreatic, which assist in digestion; the lymph and the fat, which lubricate the parts; the mucus, which protects them from acid substances; the nervous fluid, which forms a very conspicuous link between body and mind; the seminal fluid employed in generation to propagate the species; and the lacteal intended for some while to support the young after they emerge from the fetal state.

167
Some mat-
ters secreted
at different
periods of
life for par-
ticular
purposes.

The saliva is a fluid that mixes with the food in the time of mastication. In man it is secreted from the parotid, the sublingual, and submaxillary glands (Q); it is watery and somewhat viscid; it is found to retard and moderate fermentation: it has sometimes a tendency to form calculi like the urine. By these concretions it incrusts the teeth and sometimes obstructs the salivary ducts. It is the seat of the rabies canina.

168
The saliva.

Upon first examination the gastric liquor seems to possess a solvent power upon animal and vegetable substances without any great preference of affinity. The reason is, it varies according to the nature of the aliment; "it is sometimes acid, sometimes insipid. Brugnatelli has found (says Chapuis) in the gastric juice of carnivorous birds and some others a disengaged acid, a resin, and an animal substance, united with a small quantity of common salt. The gastric juice of ruminating animals contains ammoniac, an extractive animal substance, and common salt. In our time the phosphoric acid has been found disengaged in the gastric juice" of the graminivorous kinds.

169
Concre-
tions form-
ed by it.

170
The gastric
juice.

"The bile secreted by the liver is glutinous or imperfectly fluid like oil, of a very bitter taste, a green colour inclining to yellow, and froths by agitation like the solution of soap. Its constituent principles are water, a spiritus rectior, a coagulable lymph, a resinous oil,

171
The bile.

(Q) These glands are very rarely met with in birds. It is mentioned as a singular circumstance in the demoiselle of Numidia, that "in the lower beak, on both sides of the tongue, under the inward tunicle of the mouth, there were found two glandulous bodies, from whence proceeded several lympheducts which opened into the mouth, and there discharged, being squeezed, a white and viscous humour. There were two of them towards the upper part a great deal bigger than the others. The tongue was fleshy at top and cartilaginous underneath, as in hens.

"The tunicle of the palate was rough, with a great number of little nipples and of hard and membranous points. It likewise included a glandulous body, which shot forth two great ducts opening into the mouth. There was discovered a great quantity of other little glands at the sides of the larynx, which had also some lympheducts." *Anat. Descript. of the Demois. of Num. by the French Academy.*

Secretion. oil, and soda. The resinous part differs from vegetable resins; because these do not form a soap with fixed alkalis; because they are more acid and inflammable; and because the animal resin melts at the temperature of 40 degrees, and acquires a fluidity similar to that of fat. From fat it differs in not being soluble in cold alcohol, in which respect it approaches to spermaceti, which alcohol cannot dissolve without heat.

172
Concrete
fusions form-
ed by it.

Bile, like other soaps, removes spots of oil from these substances to which they are adherent; when its passages are obstructed the motion of the intestines becomes languid. It is neither alkaline nor highly putrescent. In putrefaction it yields something of a milky colour; the fossil alkali precipitates from it a green sediment; and with distilled vinegar it produces a mixture neither acid nor sweet. Like saliva and urine, it has a tendency to form concretions which are called *biliary calculi* or *gall stones*. They are sometimes found of an irregular texture, of a brown, black, yellowish, or greenish colour. They sometimes consist of transparent crystalline laminae, like mica or talc, and are sometimes radiated from the centre to the circumference. They are always inflammable, of a more solid consistence than the generality of animal oils, and resemble spermaceti both in their solidity and crystallization; they are soluble in ardent spirit when assisted by a moderate heat: the warm solution, when filtered, deposits by cooling a number of laminated white brilliant crystals, such as Poulletier de la Salle found in the bile, and which have been compared to the salt of benzoïn, the concrete acid of borax, and to spermaceti. Many of their characters indicate that they are a substance of the same nature with the last mentioned. Fourcroy found that the substance of which these crystals are composed exists not only in the crystallized gall-stones or bile; he observed it to a very considerable degree in a human liver which had been exposed to the air for several years, and had lost its volatile parts by putrefaction. He detected it also in a saponaceous form in bodies which had been many years buried under ground; and lately Dr Pearson of London has artificially converted the muscular fibre into a substance of a similar kind, highly inflammable, and resembling spermaceti (r).

173
Muscular
fibre con-
veyed into
fat.

174
The pan-
creatic
juice.

The pancreatic juice resembles the saliva, and was examined in the last century, with a good deal of care, by De Graaf and Swammerdam. It has often been observed forming stony concretions (s).

175
The lymph

The lymph consists chiefly of water, but, like the serous part of the blood, contains a substance which is

coagulable by heat, by acids, and by spirit of wine. It is found in the cellular membrane, in the ventricles of the brain, in the pericardium, on the surface of the pleura, in the abdomen, in the bursa mucosa, and in the joints under the name of *synovia*, where it has more than an ordinary degree of viscosity and of the lubricating quality. Sometimes, when it stagnates in the sheaths of the tendons and oursements, it acquires a thickness and forms indolent transparent tumors, which become at last gelatinous. It is secreted chiefly by arteries.

Secretion.

176

Animal fat is a substance of a nature similar to those oils which are called *f* in the vegetable kingdom. Its colour is usually white, sometimes yellow, and its taste insipid. Its consistence is various in different animals. In cetaceous animals and fishes it is nearly fluid: in carnivorous animals more fluid than in the frugivorous: in birds, finer, sweeter, and more unctuous, and generally less solid, than in quadrupeds. In the same animal it is more fluid near the kidneys and under the skin than in the vicinity of the moveable viscera. As the animal grows old it becomes yellower and more solid; and in most animals is more copious in winter than in summer. In man and some other animals, it is collected in particular particles of the cellular membrane, accumulated in great quantities in the groin, in the axilla, in the epiploon around the kidneys and around the blood vessels: it is likewise secreted on the surface of the skin which it protects from acrid substances, and where it sometimes concretes, often from a want of cleanliness, in the form of small worms. In cetaceous animals and fishes it is generally disposed in certain reservoirs, such as the cavity of the cranium and the vertebrae; in some it is chiefly confined to the liver; in serpents, insects, and worms, to the viscera of the lower belly, where it is disposed in small lumps, and only a small quantity found on the muscles and under the skin: in frogs it is collected in certain bags which diverge, as it were, from a common trunk, and seem like appendages to the ovaria and testes. In many places it seems to be secreted by organic pores, and under the surface of the skin by glands. It is accumulated from a diminution of perspiration, from the nature of the aliments, from morbid affection, and from idiosyncrasy. It is of the same nature as the fixed oil of plants; and Lorry has found a striking analogy between it and the bile*.

* See Four-
croy.

180
Its uses.

It is a bad conductor of heat, and preserves the warmth of those regions where it is situated. It is more adhesive and less apt to evaporate than water, and is therefore a better lubricating fluid. When re-absorbed, it counteracts the saline impregnation if too copious;

4

(r) The means which he uses is digestion in water; and the process supposes a previous acquaintance with what is common and what peculiar to the fibre and the fat. He maintains that the fibre is entirely composed of carbone, oxygene, hydrogene, and azote. In a high temperature these are decomposed, or at least separated, without producing fat. But when the fibre is kept in water in a low temperature, the carbone unites with the hydrogene of the water, and forms a fat resembling spermaceti, and highly inflammable. Part of the oxygene, too, uniting with azote, forms the nitric acid; and part of the azote uniting with the hydrogene constitutes ammonia; so that three substances are thus formed.

(s) De Graaf was of opinion, that calculi might be formed in all glands. He had seen them above twenty times in the pineal gland, that was long thought the residence of the soul:—He says, too, that they occur more frequently in the pineal gland of Frenchmen than of Dutchmen; and very pleasantly assigns this reason, that the volatile spirit of a Frenchman requires more blast than that of a Hollander. *De Saco Pancreatico*, cap. 7.

Secretion: copious; and its nutritive power is as three to one when compared to that of the muscular fibre. These properties may partly serve to explain its uses around the several branches of the blood vessels in those parts which require warmth, and in those which are anywise exposed to motion. They will likewise account for its being more copious in winter than in summer (τ); and for its being found in great quantities in the marmot, the dormouse, in the bear, and those animals in general which are constrained to along abstinence. It forms sometimes scatomatous tumors, and contains the sebatic acid, which acts readily on lead, copper, and iron.

181
Vegetable fat.

The vegetable fat is contained chiefly in the fruit; and is known by the names of *fat oil*, *sweet oil* and *oil by expression*. It freezes in different degrees of heat, and varies according to the nature of the plant by which it is afforded.

182
The mucus.

The mucus is more viscid, than the lymph, and is not coagulable by fire or alcohol. It is mild, not disposed to corruption, nor soluble in water. This secretion is performed by glands. These glands, in the pulmonary phthisis, secrete often a mucus that resembles pus, and occasions a suspicion of ulcers where there are none. Mucus is found in the nose, through the whole length of the alimentary canal from the mouth to the anus, in the aspera arteria, in the bronchia, in the kidneys, ureters, bladder, and most of all in the urethra. It forms hard stony concretions sometimes in the lungs.

183
Concretions formed by it.

The feminal fluid has been seldom the subject of chemical analysis. It is heavier than water, soluble in urine, deliquesces in air and with heat, it hardens with the fixed alkali, and is not coagulable by alcohol. It contains a number of animalcules; and in the system in which it is secreted, it affects the passions, the manners, and the voice, the taste of the muscles, the secretion of fat, and the growth of the hair. In many fishes this fluid is contained in a sort of bags. In most animals it is secreted by glands, which are called *testes*, and is accumulated in the *vasa deferentia*, or where they exist, in the feminal vesicles. Of these vesicles Swammerdam observed long ago, that in the scorpion they were probably "adapted by nature to secrete a feminal matter different from that supplied by the testicles; they are largely (he says) supplied with glandules to answer that purpose, and consist of a considerably thick and spongy substance." Mr Hunter since has endeavoured to show that they secrete a particular fluid in all animals.

184
The feminal fluid.

185
The nervous fluid.

So little are we acquainted with the nervous fluid, that some have doubted of its existence. The discovery, however, of Galvani, and the numerous experiments that have since been making on animal electricity, leave us not without all hope that something yet may be known of its properties that will greatly illustrate several phenomena in the animal economy.

186
The milky fluid.

The lacteal secretion is generally confined to one sex, and is peculiar to the class of mammalia, though something similar may perhaps be secreted in the crops of pigeons.

It would be impossible here to enumerate or to tell the uses of all the different kinds of secretions in living bodies. We cannot enumerate all that we know without running into tedious detail. The essential oils, the camphor, the gums, the balsams, the resins, and many others, are various secretions of the vegetable kingdom. Each species of plant and animal has generally some peculiar secretion; and this secretion in the individual has often some distinguishing quality, discoverable by taste, by colour, or by smell. These different secretions have likewise each their particular uses. We know the intention of the oily juice with which the bird dresses its feathers, of the glutinous fluid of the fish, of the viscid mucilage of the snail; we see the purpose for which the viper sometimes employs its virulent humour, and for which the scuttlefish ejects its ink: but yet we know only in part.

Secretion:
187
Each species has peculiar secretions.

The difference among the various secretions of the same system seem principally owing to a difference of stimulants, and to some difference in the action, the form and the irritable power of the secretory organ. Passions of the mind very often affect the secretions; and it frequently happens that passion and medicine affect one secretory organ and not another. It is therefore probable that the organs of secretion, and the smallest fibre is an organ of this kind: we say, it is probable that the organs of secretion, like the eye, the ear, and all the different organs of sense, are each affected in some measure by peculiar stimulants; as the stomach by hunger, by fauces the thirst, and the genital organs by venereal orgasmus.

188
Cause of difference among the secretions.

Fermentative mixture, and some original impregnation of the organs, have also been brought to explain the several phenomena of secretion. We conclude with observing, that however much the various fluids of living bodies may differ in appearance, chemical analysis has generally reduced them to a water, a gluten, a saline impregnation, and an oil.

189
To what reduced by chemical analysis.

SECT. VII. *Integumentation.*

ALL living bodies are furnished with one, two, or with more integuments, which are prepared by secretory organs, and which are a defence against those injuries to which their situation is commonly exposed. Of these integuments, some prevent the dissipation of the fluids, some again resist acrid and corrosive substances, some are indigestible in the stomach, and some are seemingly incorruptible in the earth. By these properties they preserve feeds and the ova of insects for a number of years, waiting the change of soil or of season. They protect both from the action of weak membranous stomachs, and make those animals who choose to swallow them contribute likewise to their propagation. The gelatinous substance ejected by birds, and called the *tremella-nestæ* or *starfall*, we have lately found, by numerous experiments, to be a substance of this kind. It is nothing else than the oviducts of frogs, which, as the embryo in form of an egg moves along their winding canal, are intended by nature to secrete that transparent and viscid glaire

190
Integumentation.

191
Some integuments indigestible in the stomach, and resist corruption in the earth.

(τ) The efficient cause may be diminished by perspiration.

Integumenta-
tion. which constitutes the albuminous part of the ovum, and feeds and protects the embryo in water (u).

192 Some integuments form a defence by their hardness; Some integuments are chiefly useful by their strength and hardness. The shells of the beetle are an excellent defence for the membranous wings which the creature is seen to pack up in folds when it inclines to creep into the earth. The shell of the snail lodges the intestines (x) when the animal comes forth to search for its food, and it furnishes a safe retreat for the body when any danger is threatened from without. Some animals, confined to their shells, can open and close them by a muscular power; and some shells, like the scales observed on fishes and insects, are disposed into plates, so as to be no hinderance to motion. Several insects which spend a part of their time in the water always compose a shell for themselves where it is needful. The usual materials are sand, straws, or mud, which they cement by a viscid secretion. The shells of most insects are corneous. Swammerdam found that cretaceous shells are composed of layers of indurated membranes, and that they are sometimes covered with a cuticle.

193 By their hair, down, or feathers; Some integuments are covered with feathers, some with hair or a thick down. Besides many other obvious uses of these coverings, they serve in general to repel insects; and being bad conductors of heat, maintain a genial and necessary warmth.

194 By their prickles; When the integuments are covered with prickles, they repel attacks by the strength of their points, or by the venom which they infuse, as the stings of nettles and the downs of some insects and plants.

195 By a viscid secretion; When they are moistened with a viscid secretion, they preserve the necessary softness of the parts, prevent evaporation, resist acrimony, enable plants to destroy their enemies, and assist the snail in performing its motions.

196 By their effluvia; Both plants and animals, but particularly the former, are often protected by an odorous effluvia from their integuments. This effluvia is the finer part of their volatile oil, always inflammable, and so subtle, that the continual emission of it from wood or flowers does not sensibly diminish their weight. To this fragrance it is owing, that the deadly nightshade, the henbane, hounds-tongue, and many others, are seen on almost every high road untouched by animals. The mancinelle-tree of the West Indies emits so very dangerous vapours, that the natives poison their arrows with its juices, and those have died who have ventured to sleep under its shade. The lobelia longiflora of America produces a suffocating oppression in the breast of those who respire in its vicinity. The return of a periodical disorder has been attributed to the exhalation of the rhus toxica dendron. Every one knows, says Chaptal, the effects of musk and oriental saffron on certain persons. Ingenhousz mentions a young lady whose death was occasioned by the smell of lilies; and Triller re-

ports an instance of another who died in consequence of the smell of violets. The selection of grasses by different animals seems to be owing to the manner in which the volatile aroma affects their senses. But of all the vegetable exhalations known, those emitted by the bohun-upas, or poison tree of Java, are the most remarkable. For many miles round no animal can breathe the air, no plant dares to peep from the soil, the fishes die in the poisoned stream, and the birds that venture athwart the atmosphere with despairing shrieks sink down lifeless. Such often is the use of the fragrant oils in the vegetable economy. The shrubs and trees that are covered with thorns are in general a grateful food to animals. They generously avow their manner of attack, and scorn the dark assassination by poison.

197 By their colour; The various colours of the integuments, as well as the aroma, is a species of defence. "Caterpillars which feed on leaves (says Darwin) are generally green; and earth worms the colour of the earth which they inhabit. Butterflies which frequent flowers are coloured like them. Small birds which frequent hedges have greenish backs like the leaves, and light coloured bellies like the sky, and are hence less visible to the hawk who passes under them or over them. Those birds which are much amongst flowers as the goldfinch are furnished with vivid colours. The lark, partridge, hare, are the colour of dry vegetables or earth on which they rest; and frogs vary their colour with the mud of the streams which they frequent (y), and those which live on trees are green. Fish which are generally suspended in the water, and swallows which are generally suspended in the air, have their backs the colour of the distant ground, and their bellies of the sky." The sphinx-convolvuli, or unicorn-moth, resembles in colour the flower on which it rests; and among plants, the nectary and petals of the ophrys, and of some kinds of the delphinium, resemble both in form and colour the insects which plunder them, and thus sometimes escape from their enemies by having the appearance of being pre-occupied. From colour being thus employed as a defence, many animals vary their colours with the seasons and circumstances; and those which are of different colours in summer according to the places which they inhabit, do all in winter assume in common the colour of the snow.

198 By their change of colour. But a change of colour is not the only change of the integuments. As the outmost are often insensible to stimulants, and for obvious reasons possess little of the vital principle, in all cases where they cannot be enlarged to admit an additional increase of growth, or where they are not furnished with necessary organs to repair those injuries which they may suffer from disease or accident, the body is endowed by nature with a power to throw them off, and to produce others in their stead (z). For this reason we see the tree casting annually its exterior bark, the lobster his shell, the bird

(u) We have often inflated the oviducts of frogs, and dried them; and afterwards putting small pieces of them into water, have seen them swell in a few hours to a large size, and forming the tremella-mofoe, or starfall.

(x) This snail is found in our gardens, and carries its shell, including the intestines, upon its back.

(y) The same is the case with many fishes that live in lakes.

(z) Several small animals in changing their integuments change likewise the interior coat of the alimentary canal, which they void with the fæces.

Irritability. 200
Toads eat the skin.
bird his feathers, the quadruped his hair, and sometimes his horns, the serpent his skin, and man himself renewing the scales of the epidermis. These changes usually take place once a-year, twice frequently with respect to serpents, and oftener in toads, who have been observed to devour the skin which they throw off. All the integuments of ova and seeds, being wholly the production of parental organs, neither are nor can be repaired.

SECT. VIII. *Irritability.*

Irritability. 201
Is that property of the living fibre by which it acts in consequence of stimulants. Being one of the great causes of motion in living bodies, no property has excited more wonder, been the cause of more error, or exhibits such a number of striking phenomena to the senses. These effects, however, have arisen rather from the nature of the stimulants than from any thing mysterious in irritability. Many of the stimulants by which this property in bodies is displayed are often invisible, unknown, or unthought of, and men being conscious that a number of their motions proceed from a stimulant, that is, under the direction of a mental power, they readily conclude from a sort of analogy, that every motion in plant and insect that seems to answer a useful purpose, and is caused by some invisible stimulant, is the consequence of mind directing from within. They further suppose that irritability is in all cases the consequence of nerves, which are those organs which nature has employed in the animal kingdom to convey stimuli between body and mind. These singular conclusions have led to others that are less admissible even than themselves. It has been imagined that creatures the most stupid possess within them a principle of mind that is incapable of further improvement, but which notwithstanding is in many respects superior to reason, and a surer guide in whatever relates to self-preservation or that of the species: it enables the animal to predict without foresight, and to act rationally without intelligence. This wondrous principle has been called instinct: and in order to account for some of the singular phenomena of vegeta-

202
The phenomena of irritability have led to strange conclusions.

203
Some of these conclusions.

bles, a share of it has graciously been allowed to plants; which having become favourites of fate, have been also presented with the privilege of sensation, permitted to fall in love, and to marry, and on some occasions to exercise the faculty of volition.

At these concessions the metaphysician will naturally smile. He knows how many impose on themselves by the mere sound of their own words, as if by calling the snow black they were to discover a new property; which curious discovery would turn out at last to be only a gross ignorance of language, and the foolish misapplication of a syllable. He who has studied the philosophy of mind, and been accustomed to view objects through another medium than the magic colourings of passion and of fancy, readily perceives a something of absurdity in ascribing such wisdom to plants and insects. With respect to animals, these gentlemen do not recollect that voluntary actions are of two kinds, as they proceed from design or propensity; that in performing one of these kinds the mind itself has an object in view, and is properly the source whence they originate; but that in the other the mind is merely a secondary agent, is acting under the influence of stimulants, is often not aware of the consequences, or although aware is often so infatuated as not to regard them, however fatal. It is generally well known to the naturalist, that not a few of these propensities arise from the form and structure of the body, from the manner in which the optic nerve is affected by colours, the olfactory by smells, the gustatory by tastes and auditory by sounds; from the different ways in which the fauces are affected by thirst, the stomach by hunger, and the genital parts by venereal orgasmus.

Besides these and other propensities which operate as stimulants in the system itself, the naturalist has found that light, heat, and moisture, in various degrees, from absolute darkness, coldness, and dryness, act as stimulants upon living bodies: he has experienced that electricity is a general agent, that several plants emit flashes (A), and that some animals even give shocks resembling the electric. He has made it probable that

it

4 U 2

(A) "In Sweden (says the author of the *Loves of the Plants*) a very curious phenomenon has been observed on certain flowers by M. Haggeren, lecturer on natural philosophy. One evening he perceived a faint flash of light dart from a marigold: surprised at such an uncommon appearance, he resolved to examine it with attention; and to be assured that it was no deception of the eye, he placed a man near him with orders to make a signal at the moment when he observed the light. They both saw it constantly at the same moment; the light was most brilliant on marigolds of an orange or flame colour, but scarcely visible on pale ones: the flash was frequently seen on the same flower two or three times in quick succession, but more commonly at intervals of several minutes; and when several flowers in the same place emitted their light together, it could be observed at a considerable distance. This phenomenon was remarked in the months of July and August at sunset, and for half an hour after when the atmosphere was clear, but after a rainy day or when the atmosphere was loaded with vapours nothing of it was seen. The following flowers emitted flashes more or less vivid in this order: The marigold, garden nasturtium, orange lily, African marigold; sometimes it was observed on the sun-flowers; but bright, yellow, or flame colour, seemed in general necessary for the production of this light, for it was never seen on the flowers of any other colour. The flowers were carefully examined with a microscope without any insects or phosphoric worms being found. M. Haggeren, after having observed the flash from the orange-lily, the anthera of which are a considerable space distant from the petals, found that the light proceeded from the petals only; whence he concludes, that this electric light is caused by the pollen wheel, in flying off, is scattered upon the petals (*Observ. Physique par M. Rozier*, vol. xxxiii. p. 111.)"—Addition to the note on *Tropæolum*, the *Loves of the Plants*. The author of this beautiful poem supposes, that the time of the twilight is sometimes extended by different bodies emitting the light which they had absorbed during the day.

irritability. it produces all the wonders of crystallization; and that the cause of chemical affinity, and of all the phenomena displayed by the magnet, is not simply a modification, is at least akin to it. In the male parts of plant and animal, he has seen both the fluid and the pollen that give the stimulus in generation, and are accompanied with so extraordinary changes in the system. He has found that much of the vegetable economy, and that even the function of generation itself, as the development of the fecundating powder, and its application to the female organ, is partly carried on by wind, heat, and other such agents. He has reason to conjecture that many general agents in nature are yet unknown. By the help of chemistry, he has found out lately a considerable number which are called gases, which are of the very highest importance in both the animal and vegetable economy, and which, like the aromas of plants, or the causes of contagion, produce their effects without being visible. It is only, too, of a late date that the celebrated professor Galvani of Bologna has excited so much curiosity through Europe, by the discovery of a certain stimulus that resides in the nerves, that passes along electric conductors, and which by a certain application of metals occasions a vivid flash in the eye, convulses the body of a living frog, and rouses the detached limbs into action. The change of colour in the integuments according to different seasons and circumstances, though it answer a rational and useful purpose, proceeds from a cause that does not seem to be very well known. Even many agents which are not visible, nor yet unknown, exert their influence in a secret manner, so as not be obvious to the senses. It is generally known that many singular movements of plants are owing to heat, many to light, and several to moisture. The barley-corn is often observed to creep on the ground by means of its awn, which dilates and contracts according to the different degrees of moisture. The wild oat, employed as an hygrometer, moves through the barn, travels through the fields, nor ceases to be changing its situation till its beard fall off, or till it meet with a soil where it conveniently may strike root. Upon a similar principle of motion, the ingenious Edgeworth constructed an automaton which moved through a room which it inhabited. It is easily conceived how these singular effects, arising from causes that are unknown, invisible, or unthought of, should give birth to the notions of witchcraft and of instinct, and impress the fancy with an idea of something resembling sensation and volition in the vegetable kingdom. These agents, whether invisible, unknown, or unthought of, directed by regular and uniform laws under the great Author of nature, produce effects that indicate preference, wisdom, and design, and causing a transient or permanent propensity in the mental part, frequently controul by restless sway the finite minds

that reside in matter. These minds, in a living body, have generally been found accompanied with some system of nerves; and these nerves happening with equal facility and promptness to convey stimuli from the mind to the body and the body to the mind, the great difficulty has been to determine with respect to others when the action proceeds solely from design, solely from propensity, or from design and propensity together. The uniform conduct of the brute creation would seem to imply that their mind has little of inventive power; that it generally acts from the impulse of propensity; and that its manners are varied, not in consequence of a change of sentiments, but from the induction of new habits, and the application of new stimulants.

Irritability.
209
Brutes act
chiefly
from propen-
sity.

It has been observed, that in all animals the vigour of mind has some relation to the quantity of brain, and to the perfection of its organization; and that the acuteness of the different senses is generally proportioned to the quantity of nerve bestowed on their organs (b). Man has a greater proportion of brain than any other animal; but many an animal has a much greater proportion of nerve bestowed on different organs of sense. Many animals have therefore acuter senses than man; but man has a greater vigour of mind than any other animal on this globe.

210

ture of
their or-
gans.

The brain of quadrupeds is somewhat similar to that of man, but proportionally smaller, and not perhaps so well organized. Willis has observed, that among animals the structure of the cerebrum is more variable than that of the cerebellum; that the former generally furnishes nerves to the voluntary muscles, and the latter with the medulla oblongata to the involuntary. He has likewise remarked, that the round prominences commonly called the nates and testes are large in the quadrupeds, which are active and vigorous, and in some measure able to procure their own subsistence at birth; that the tuber annulare is large in the quadrupeds that are distinguished for their sagacity; that wherever the tuber annulare is small, the prominences are large, and wherever it is large the prominences are small. From these observations he has concluded that the tuber annulare is the seat of genius, and the round prominences the seat of what has been called instinct (c).

211
The brain
of quadru-
peds

The brain of birds is seemingly the reverse of the human brain; the cortical substance the interior, and the ventricles are situated in the white part on the outside. In the brain of the bird there are no circumvolutions like the intestines, no fœmix, corpus callosum, nor corpora striata.

212
And birds.

The brain of fishes is in many respects similar in its structure to the brain of birds. It is very small in proportion to their body, and is generally surrounded with an oily matter. In one genus of fishes, the gadus, Dr Monro found spheroidal bodies between the dura

213
The brain
of fishes.

(b) The acuteness of the senses depends upon the readiness with which their organs are affected by stimuli. This readiness depends on irritability. It is not necessarily connected with mind, nor should it ever be confounded with perception, which in classical language signifies a property of the mental principle.

(c) Few perhaps who have dissected different animals, and who, besides a number of structures have seen a variety of tubercles and lobes existing in the brain, will be rash in ascribing to any one of them one particular office. The pineal gland was for some time thought the seat of the soul. It was afterwards found to be often

ten

Irritability. dura and pia mater, and covering the greater part of the nerves like a coat of mail. The two senses, seeing and hearing, in many fishes are often acute. By laying one ear on the water, and striking the surface at some distance, this element is found to be a better conductor of sound than even the air.

214
Of reptiles. The reptile tribes have very little brain, and like the fishes have no ganglions upon their nerves.

215
Of insects. Most insects have no brain at all, but a nervous cord that is full of ganglions, that runs from one extremity to the other, and is denominated the spinal marrow. This knotty cord, however, is not marrow; the insect has nothing resembling a spine; and the situation of the cord in the animal is often not along the back but the breast. In the silk-worm, and most other insects, this cord is in contact with the alimentary canal; and the first ganglion, which is sometimes called the brain, though not in the head, divides, in order to give a passage to the stomach, and again unites in a second ganglion. Swammerdam found in a species of snail a brain with two lobes, in contact with the stomach, moveable by muscles, and without a fixed place in the body.

216
A moveable brain in a species of snail.
217
Polypes, The polypes exhibit no appearance of brain or of nerve, as in other animals. Their skin, however, is observed to be full of a number of small granularly bodies, which are connected by a glareous matter that resembles a thread. Like rows of bead-strings, they extend from one extremity to the other, and along the arms. Trembley learned from a number of experiments that they received their colour from the food, and therefore supposed them to be vesicles or glands. If not like the tuberous nerves of the insects, they at least are not very different in appearance from the

nerves of the gadus that are covered with a number of spheroidal bodies like a coat of mail.

Some things would insinuate that a nervous system does not seem to be necessarily connected with mind. The stimuli of nerves may be brought into action by other causes besides mind. Even many nerves are not subjected to the influence of mind; and the mind often by its own inattention may lose the power which it originally possessed over nerves. Many persons can move the muscles of the ear, and others may have lost that power through neglect. After Fontana had observed that the heart was a voluntary muscle in a wheel polype, he learned to retard and accelerate the motions of his own at pleasure. If some nerves, from a sort of prescription, thus cease to be obedient to the power of mind, others by frequent service and habit become so obedient as to convey their stimuli to the muscles almost without the consciousness of mind. The motions excited by the stimuli of nerves are in many cases exceedingly rapid. These may be seen in the wings of most insects, but are most noticed in dancers, tumblers, and apes, and all those animals that are exhibited for feats of agility.

The motions which we see excited in the body by the stimuli of nerves have often been so vigorous and prompt, as to have torn the muscle from the bone, and to have broken the bone itself. They often affect the organs of secretion, have often unhinged the fabric of the system, occasioned death, and accounted for the miracles that have been ascribed to the power of fancy. The prompt motions of what have been named sensitive plants seem owing to a different species of stimulants acting on extremely irritable fibres (n).

In the animal kingdom all muscles in the time of action

(D) In many instances the prompt motions of animals seem more owing to the irritability of their fibres than to what has been called the sensibility of their nerves. The poet was mistaken when he supposed that the mangled insect would feel as sensibly as a mangled giant. When the gad-fly fixes fairly on the hand, you may cut off its wings, its legs, its antennæ, and a part of the lower division of its body, without disturbing its gratification, or apparently occasioning to it much trouble.

action are observed to discharge a quantity of their blood and those muscles which are naturally white are the most irritable. In all living bodies, the irritable power will cease to obey the action of a stimulant if either long or violently applied. After exercise therefore, the irritable fibre requires rest, after heat cold, after waking sleep, before it again becomes submissive to the action of the stimulant that overwhelmed it. This is the reason that in plants and animals there are certain exertions and functions of the system that can only be continued at intervals and seasons. The natural stimuli of involuntary muscles continue to act, and the muscles continue to obey through life.

The organs of sense were formed to mark the difference of stimulants; yet living bodies are affected by light without having eyes, by sounds without having ears, by odorous effluvia without having smell, and by sapid bodies without having taste. It is easily conceived how these objects, by their inherent properties or motion, may produce a confused sort of excitement in every highly irritable fibre. But the organs of sense are peculiarly fitted to receive accurate and distinct impressions from each of those objects; and these different impressions seem not to arise from any difference in the kind of nerves by which they are received. All the difference that has been observed arises from the structure of the organ itself, and from the manner in which the nerve is distributed through it. Other parts of the animal body, as the stomach, the fauces, and genital organs, are thus affected by particular stimulants; and many animals, and even vegetables, may be affected in various manners, and by various stimulants, of which neither our feelings nor our senses can give intimation of any thing analogous.

With respect to the several organs of sense, some animals have many eyes without any motion, and some animals have few eyes with varieties of motion. The entrance to the ear in some animals is from the mouth, as happens in the frog; and the bones of the ear are without the cranium, as in some fishes. The sense of smelling is found in the nose: this sense is astonishing in dogs; and even sheep, in distinguishing their lambs, trust to it more than seeing or hearing. The sense of taste is far from being general; and the sense of touch can hardly be said to reside peculiarly in any one organ.

SECT. IX. Motion.

IRRITABILITY is one of the great forces of motion in all living bodies; and this power is brought into action immediately by nerves or some other stimulants. Locomotion here is principally considered; for altho' the kinds of internal motion employed in secretion and the other functions be as remarkable, in the eye of the philosopher they have not so generally attracted the attention. Most animals are capable by nature of changing the place which their body occupies; for this reason the irritable fibres being formed into bundles, which are called *muscles*, are in most animals attached to bones, cartilages, or hard integuments, which they move as levers: these levers, with their muscles attached, are in most cases formed into wings, fins, and legs of various kinds, and are employed in performing

the motions of flying, swimming, walking, leaping, and creeping. So very necessary, in the opinion of some of the ancients, was one or other of these instruments to progressive motion, that the movement of the serpent was often ascribed to a preternatural cause, was supposed to resemble the *incessus deorum*, and procured to the animal one of the highest and most honourable ranks among the emblematic kinds of divinities. Even Moses himself, who was unwilling to allow it the character of an agathodæmon or good genius, was yet so puzzled at its being able to move without feet, that he pronounces it a tool of the devil; and says that it was deprived of its feet by a curse from heaven for seducing mankind into idolatry. Notwithstanding, however, the surprize that has been occasioned by the singular movement, the motion of snails, though not so rapid, is in many respects as extraordinary: they adhere by a certain viscid secretion, on dry ground this secretion forms a pavement over which they glide; and they proceed by the action of muscles without bone, cartilage, or shell, to which these muscles can be attached.

No animal walks without legs or flies without wings (E): but there are many that swim without fins, and that leap and creep without any legs. The rapidity of movement is not proportioned to the number of instruments that are employed: if the spout-fish be observed to move slowly with one leg, the sea-urchin moves still slower with many thousands; the oyster moves by squirting out water; the scallop by the jerk of its shell, and when in the water it rises to the surface and sails before the wind.

Many animals are formed by nature to fly, walk, leap, and swim: the fate of those is rather uncommon whose muscles or feet are by nature attached to their integuments; the lobster is obliged to throw off its shell, and the caterpillar all its feet with the skin, and in that situation to remain stationary till it receive new instruments of motion.

Whoever has read the celebrated work *De Motu Animalium*, needs not to be told that, besides the organs which are here mentioned, the form, the structure, and even the specific gravity of the body, as depending on the nature of the bones and muscles, or as varied by air, vesicles, and bubbles, with a great variety of other circumstances, are necessary to explain the different phenomena of locomotion.

As to vegetable motions, they evidently depend on external agents: The motion of the wild oat has been mentioned; the wings of seeds only fit them to be carried by the wind, their specific gravity to float in the water, and their legs or tentacula to adhere to bodies that are in motion; the singular motions which have been ascribed to sleeping, to waking, to sensation, and volition, in the vegetable kingdom, seem only the consequence of light, heat, moisture, and such stimulants, acting invisibly or with secret influence; the opening and closing of the meteoric flowers are always correspondent to the states of the atmosphere; and the opening and closing of the equinoctial and tropic flowers, to the light, the length, or shortness of the day.

nature may be extended in the different species of plants and animals. It is known, however, that the lamb and the dove can be made carnivorous; and that the hawk, laying aside his ferocity, can be brought by art to live upon grain.

Habit.

SECT. X. *Habit.*

235
Habit; **Habit** here deviates a little from its usual meaning. We employ it to signify that principle in living bodies by which they accommodate themselves to circumstances, assume as it were a different nature, and in many respects undergo a species of transformation.

Of all the effects of this singular principle, the most wonderful are those which are seen to take place with respect to generation. The fact is far from being new to the naturalist, that certain animals, oviparous at one season, are viviparous at another. This indicated much of accommodating power, though far inferior to what has been since witnessed and displayed: for who from all this could suspect, that any animal which usually propagates by an intercourse of sexes, could in any circumstance accommodate so far as to multiply its species another way. Bonnet of Geneva, however, has discovered, that the puceron or vine sucker, which generally propagates by an intercourse of sexes, is not only oviparous at one period and viviparous at another, but in all cases where the union of the sexes is not to be obtained, can easily accomplish all the purposes of generation without it. Similar experiments have likewise proved, that many plants can bring to maturity a productive seed, though the male parts of the flower be destroyed before they can in the usual way have any impregnating effect on the female. In this case the conclusions drawn have been somewhat new. From these experiments it has been inferred, that the sexual system is ill-founded, and that most of the learned naturalists of Europe are on this subject labouring at present under a mistake. This reasoning, however, is not satisfactory: for why, it might be asked, in the vegetable kingdom more than in the animal, should the mode of generation be necessarily uniform? Tho' some plants may, like some animals, propagate without sexual distinctions, the conclusion is not logical that these distinctions are useless in all; and though some few may, in particular instances, propagate without that impregnation to which they were accustomed, will any one demonstrate, that accommodating nature does not here as in the puceron adopt a new method to accomplish her designs?

241
How far it accommodates with respect to generation.

236
Its effects on vegetables; So very much do some individuals of the vegetable tribe accommodate themselves to different situations, to soil, to climate, and the state of cultivation, that those naturalists who have not been accustomed to nice and accurate discriminations, have frequently mistaken the variations of the same plant for so many species. These variations may be daily seen by examining the plant as it grows on the mountains, in the valleys, in the garden, or in the fields; or by bringing it from a rude uncultivated state, when it sometimes lays aside its formidable prickles, and changes the colour and structure of its flowers.

237
On the constitution and integuments; In the plant and animal, the delicacy and vigour of the constitution are oftener the effects of habit and circumstance than original conformation. We have mentioned already the varying colour of the integuments, and the purpose which it serves in changing with the seasons. We may here add, that animals covered with a down or hair have it thick or thin, long or short, according to the different exigencies of climate.

238
On manners and propensities; Those changes produced on their body are accompanied with others which are the causes of new tastes, of new propensities, and new manners. At the Cape of Good Hope the ostrich inclines to sit on her eggs day and night like any other bird; but in Senegal, where the heat is great, she is somehow disposed to leave them to the sun during the day. In those countries where provisions can be found during the greatest part of the year, the bee gradually loses the propensity of laying up stores for the season of winter; and in "those countries infested with monkeys, many birds (says an amusing and instructive writer) which in other climates build in bushes and the clefts of trees, suspend their nests upon slender twigs, and by this ingenious device elude the rapacity of their enemies."

239
On man. Man, from imitation, is exposed to a great number of habits peculiar to himself; and physical causes have ingeniously been assigned for the variety of his features and complexion.

240
The extent of its effects unknown. Few experiments have yet been instituted with a view to show how far this accommodating principle in

In all living bodies, it frequently happens that several characteristic distinctions, as the colour, the features, and a number of diseases that are originally the effects of circumstance, do at last become so fixed in the system, that they are afterwards transmitted to posterity through some generations (F). With regard to animals these facts are well known; and as to vegetables, it has been observed by a pupil of Linnaeus, that the apple trees which are sent from Britain to New England blossom at first too early for the climate, and

242
Its effects lasting at & sometimes propagated.

(F) Might not these facts reasonably claim the attention of those who mean to form matrimonial connections? How many might easily entail on their posterity hale constitutions, regular features, beautiful forms, sound minds, and tempers at once uniform and cheerful, who yet, from their sordid desire of wealth or their fond admiration of high rank, bequeath to them only scorbutic habits, deformed persons, disagreeable features, mean understandings, and forbidding tempers. Excepting the more extraordinary properties of body and mind, there are few that may not in some measure be transmitted to posterity: but nature seems unwilling that what is very eminent should ever be extended to a genus or a species; and therefore the sons of Cicero and Cromwell are only two of a thousand instances that might serve to prove, that neither extensive nor eccentric geniuses can be made hereditary: In the second generation they often degenerate into minds that are weak, fatuous, or deranged; or into minds that are chiefly remarkable by their oddities and whims.

Habit. and bear no fruit; and that it is only after some years that they conform to their situation: and this circumstance, by the way, explains why roots and seeds germinate sooner when brought from southerly than when they are brought from northern latitudes. The very permanency of these effects has often been the cause of much confusion and error in philosophy: for the naturalist, mistaking the lasting though temporary qualities of habit for the real and essential qualities of species, has not unfrequently drawn conclusions from his experiments that have been contradicted by similar experiments in other circumstances. This is one of the obvious reasons why experiments exhibit to many inconsistencies and contradictions, and why we are amused with such a multitude of visionary theories about the properties of living bodies.

243
Renders
the result
of experi-
ments de-
lusive.

244
And medi-
cal pre-
scriptions
often dan-
gerous.

245
Its origin; From not attending to the numerous circumstances that induce habits, and to that general accommodating principle in living bodies, many medical prescriptions are found to be not only useless but mischievous; and many parents, by studying the health and comfort of their children, bring on habits that prove the sources of perpetual sickness or the certain prefaces of an early death.

246
Its design. The accommodating principle is one of the consequences of irritability. Its various effects arise from the actions of different stimulants on the irritable fibre; and the after-duration of these effects, from the modifications of the irritable fibre, become habitual from the frequently repeated action of the stimulants.

247
Transfor-
mation.

SECT. XI. *Transformation.*

MORE remarkably striking than any of those changes to which the plant and animal are exposed, from the variations of habit or the change of integuments, are those alterations which they undergo from metamorphosis or transformation. It has indeed been asserted, that these alterations consist in throwing off certain temporary coverings or envelopes: but there is here a want of precision in the ideas, and consequently a want of accuracy in the expression. The same persons who make this assertion inform us, that caterpillars change their skin, and many of them even several times, previous to the period of their transformation. Transformation, therefore, and a change of integuments, by their own concessions, are different things. The truth is, transformation frequently takes place independent of any change of integuments; and there is often a change of the integuments without transformation or any appearance of a new form: but a new form or change of appearance is always implied in metamorphosis or transformation. This new form is sometimes occasioned by a change of shape, consistency, and colour; as when the lobes of a seed are converted into seminal leaves. It is sometimes occasioned by a change of proportions among the parts: the proportions of a fetus, every one sees, are different from those of a full grown man; and the painter, merely by observing the proportions, represents a child, a dwarf, and a giant, on the same scale. It is sometimes occasioned by the addition of new organs; as when the enmet receives wings, and the p'ume of the

248
Not merely
a change of
temporary
envelopes.

249
In what it
consists,
and dif-
ferent
kinds of it.

feed is fed by new roots striking into the ground; or it is occasioned by a change of both the form and the organs, and their mode of operation, as happens remarkably in some insects: for though all living bodies, plants and animals without exception, undergo partial or general transformations, yet these changes are chiefly observable among insects. Many insects appear to consist of two distinct animal bodies one within the other: the exterior, a creature of an ugly form, residing in the water or under the earth, breathing by gills or sometimes by tracheæ projecting from the tail, possessing a voracious and groveling appetite, and having a system of sanguiferous vessels that circulates the blood towards the head. When all its parts decay and fall off, the creature inclosed succeeds in its stead: this often is an animal of a different form, generally lives in a different element, feeds on a different species of food, has different instruments of motion, different organs of sense, different organs of respiration, and differently situated; and being endowed with the parts of generation, inclines to gratify the sexual propensity, and produces an embryo which becomes like the first, and from which afterwards in process of time a creature is evolved similar to itself.

If the embryo or egg be deposited on a leaf, the leaf frequently is observed to bend, to wrap it in folds intended for the purpose, and to protect it from injuries and danger. If deposited in the body of an animal or plant, they accommodate themselves to its wants and necessities, and furnish a tumour which serves it for a nidus, and besides, like an uterus, supplies it with nourishment; and if deposited in the body of an insect, the creature provides for the future destination of its young charge with all the tender care of a parent, and then dies.

These circumstances, added to the great variety of forms which insects assume, render it sometimes difficult to know who is the parent. We cannot, for instance, pronounce with certainty who is the true parent of the gordius, known by the name of the *seta equina*, or hair eel. A set of experiments, which we once began with a view to throw some light on the subject, were interrupted unfortunately by an accident, and we have not since had leisure to resume them. We learned only, from a number of observations, that certain black beetles about the end of the summer months have the strongest propensity to run into the water, where they soon die; and that one or two, and sometimes three or more, of those eels gradually drop from the beetle by the anus. Whether other insects provide for the gordius in this manner we have not yet been able to determine.

The transformations of some animals are most observable in the uterus and egg. Some early transformations of the chick may be seen in the plate belonging to this article; and anatomy has often witnessed the change which happens at birth with respect to circulation, respiration, digestion, and the other functions.

If the reader wish to be much acquainted with the manners and transformations of insects, he will derive information and pleasure from consulting the plates and memoirs of Reaumur. If he wish to know their intimate structure, the laborious Swammerdam can introduce him to a new and amusing species of anatomy. This last author had before Reaumur defined and de-

scribed the kinds of transmutations among insects and some other animals. He has shown similar transmutations in plants; and in plate 46 of his Book of Nature, has compared the frog and the clove July-flower under their six different forms.

In all living bodies possessed of mind, the changes of form, as well as the change of habit and of age, are usually accompanied with new propensities, appetites, and passions. It may therefore be inferred, that we ought not to look for the cause of temper in either the brain or the nervous system; or to imagine, that the propensities, appetites, and passions, are properties of mind: they seem only affections happening to mind in consequence of stimuli and organic structure.

Microscopic observations having demonstrated, that all the forms of the plant and animal existed previously in the seed or embryo, transformation must be owing entirely to the evolution of the different parts by means of nutrition.

257 The design of transformation. What nature intends by transformation, we pretend not to say; but by means of transformation different elements are peopled, the different seasons variously adorned, and animated nature wonderfully diversified without a multiplication of beings.

SECT. XII. Generation.

258 Generation. MANY of the causes which contribute to the formation of a living body have hitherto eluded human research; may in all probability never be discovered; and perhaps are beyond human comprehension. Some philosophers, considering the extreme divisibility of matter, and learning from the microscope that transformation is but the development of certain parts that previously existed, have thence imagined that generation is somewhat analogous; that all regularly organized bodies received their form at the beginning; that the first of every genus and species contained by evolution the numerous millions of succeeding generations; and that the union of the two sexes gives only a stimulus, and brings into view forms that had existed since the world began.

259 One hypothesis, that all living bodies were formed at once, and brought into view by generation. This hypothesis has attempted to explain a thing that is unknown by what must forever remain incomprehensible to the human mind in its present state. It appeals absurdly from observation to conjecture; and supposes that bodies which are originally brought in view, which are daily augmented, frequently repaired, and sometimes renewed by organic action, do nevertheless in their first formation require an effort superior to what omnipotent power is able to perform by secondary agents.

260 Objections to this hypothesis. Had the supporters of this hypothesis considered that many herbaceous plants produce new flowers when the first set are untimely cut off, that lobsters and many a species of insect renew their limbs, and that certain polypes can raise so perfect vegetable forms as to puzzle the naturalist whether or not he should class them under plants; they would not surely have prescribed such bounds to omniscient wisdom and almighty power, or declared with such confidence what the Author of Nature, to speak with the vulgar, must necessarily perform by his own hands, or what he may intrust to secondary causes regulated by his laws.

261 Does not explain the renewal of parts. These philosophers will find it difficult to account in a very satisfactory manner for monstrous pro-

ductions, and for those changes of structure and of form which for a while continue hereditary from the influence of habit. They object to others, that all the parts of a living body are mutually dependent on one another, and that they must necessarily have been coeval or existed at once. But though every attempt that has yet been made to ascertain which of the vital organs are prior and which posterior in a living body has proved unsuccessful, it has not been demonstrated that either themselves or their functions are coeval. It may, on the contrary, be plainly demonstrated from observation, that the lungs and the stomach do not begin to perform their functions so early as the heart and the vascular system; that the heart and its system perform their functions, even with some considerable changes, immediately after birth; that the vegetable tribes are without nerves; and that brain and nerves in the animal kingdom perform more and more of their functions as the system approaches towards maturity. It has even been shown that bones will unite, and the limbs of an animal continue to be nourished without nerves; that there is a principle of life in the blood; that the heart will act under other stimuli besides that of nerves; and that sound logic does by no means require us to suppose that the first actions of the foetal heart, or the punctum saliens, are owing to the influence of stimuli from the brain, or that the brain must have existed when the heart first moved.

262 Although the minuteness and transparency of the parts may prevent us from seeing the first gradual formation of the embryo, yet every observation corroborates the opinion that it is formed by secondary causes, and through the medium of organic powers.

263 It has been asked, whether or not is the embryo formed by the joint operation of the two sexes? or is it formed entirely by the one, and brought into action by a stimulus from the other? The former of these questions supposes that each of the sexes has a seminal fluid; that some mixture takes place in the uterus, and produces an embryo, in the same manner that a neutral salt assumes a certain and determinate form. The notion implies some general and confused idea of chemical combination; but does not bespeak a very clear head, profound reflection, or much acquaintance with the nature and properties of living bodies.

264 For a long time past the most rational physiologists have generally agreed that the embryo is formed gradually and slowly in one or other of the two sexes, not by chemical combination and mixture, but a system of organs, directed by laws and prompted by stimuli, with many of which we are yet unacquainted. From the great Hippocrates downwards to Aquapendens and Harvey, the credit of furnishing the foetal embryo was almost universally given to the females of those animals which are named oviparous. Among the viviparous, appearances were such, that the female was left to contest it with the male. At last the celat of Leeuwenhoek's discoveries seemed to put an end to all doubts entertained upon the subject. He very plainly saw through his microscope that very great profusion of particles that move to and fro with amazing rapidity in the male semen. Upon this he embraced the doctrine of Hamme, who had seen them before, and supposed from their motions that these particles were not only animalcules, but the principles or rudiments

265 By one of the sexes or both. The opinion of Hippocrates, Harvey, and their followers. 266 Of Hamme, Leeuwenhoek, and their followers. 267

to this last
opinion.

red insects of that animal in whom they were formed, and that they were deposited in the uterus of the female only to be nourished and augmented in size.

What raised suspicions against this theory were the numerous animalcules discoverable by the microscope in other fluids, and that vast profusion of young embryos in those cases where never more than one or two arrive at maturity. It was an objection to it, that some females had been impregnated where the hymen remained unbroken, and where the vulva had been shut so closely as to leave only a passage for the urine. The male semen in these instances could have reached only the mouth of the uterus. It was another *, that in all birds which have no intrant penis the male semen is never sent farther than the mouth of the vulva, and that a single act of the male impregnates the whole eggs of the ovarium. A third objection is the pollen of flowers, which is not applied immediately to the seed, but often to a distant part of the vessel in which it is contained. A fourth may be taken from frogs and fishes, and all those animals whose eggs are impregnated after emission. And, lastly, Haller had observed the pullet completely formed in those eggs that were not fecundated.

* Vid.
Harv. de
Partu.

269
The former
opinion better
supported.

Supposing animalcules in every kind of prolific women, yet it frequently happens that this semen undergoes a change before it can be applied to the embryo. The semen of the frog is dissolved in water; and that which is injected disappearing suddenly after coition, would seem to intimate, that in those animals which have been examined it had met with a solvent somewhere in the uterus, and produced its effect after the change. It is now, we believe, pretty generally known, that the embryo does not commence its existence in the cavity of the uterus. De Graaf observed it on its passage down the Fallopian tube; he saw the place where it first began in the testicle of the female; and cases have occurred where it has missed the Fallopian tube, where it has fallen into the abdomen, where the placenta has been formed, and the fœtus has grown among the viscera of the lower belly.

270
More ge-
nerally
adopted.

From these facts it has been concluded, notwithstanding some feeble objections, that the female testicles are real ovaries containing eggs; that these eggs are brought into action by the stimulating power of the male semen, which is sometimes thrown into the cavity of the uterus, sometimes applied only to its mouth, and sometimes sprinkled over the egg after emission. The principal difference, therefore, that occurs between oviparous and viviparous animals, considered as such, appears to be this: the former are accustomed to eject their embryo before it escapes from the membranes of the egg; the latter retain it long in the uterus until it acquires a considerable size, until the membranes can hold it no longer, and then eject it when the membranes

271
Difference
between
oviparous
and vivi-
parous
animals
and
plants.

are burst. A plant is oviparous when it yields seed; viviparous when it produces a gem, a bud, a bulb, or an eyed root. The membranes of the seed being removed, an incipient embryo is seen through the microscope.

Genera-
tion.

Some animals, according to the season, eject the embryo enclosed in its membranes, or retain it in the uterus till the membranes are broken. These are the animals which are said to be oviparous at one period and viviparous at another. The spider-flies retain their young till they be as large as the natural size of their own bodies, and have undergone all their transformations within the expansile membranes of the egg, and an uterus as expansile as the stomach of a serpent.

272
Some ani-
mals ovi-
parous and
vivi-
parous.

In most cases generation requires a temporary union of two sexes: but it has been said, that in Senegal there is a species of shell-fish among whom this operation is the joint work of three individuals. In our own country, too, three frogs are frequently observed adhering together, though the labours of the third have generally been thought more officious than necessary. In some animals the sexual union is almost instantaneous. It constitutes nearly the business of life in the last stage of the ephemeron; and the male both of the frog and toad often continues on the back of the female not for hours and for days only but for some weeks. Upon examination it has been found, that with his fore-feet he assists the female to protrude her eggs through the windings of the oviduct; and when they at last arrive at the anus, a species of the toad has been observed to draw them out with his hind legs. These animals were probably the first of the masculine gender who practised this art. But due honour has not been ascribed to the discoverers. In former days, the generous and grateful spirit of the ancients made them ready to acknowledge their obligations to different animals for the arts of bleeding, clystering, and purging; but such is the degeneracy of modern times, that many write only to claim the discoveries of others. On this account we ought not to wonder that many accoucheurs, in publishing encomiums on their own merit, have invidiously concealed the superior pretensions of the obstetrical toad.

273
Union of
the sexes.

Among all living bodies the two sexes are generally similar, and the male sex generally distinguished by superior strength, beauty, and courage. The law, however, does not hold universally. The females of some carnivorous animals, who are left by the male to provide for their offspring, are larger, stronger, and more ferocious than he. Among some insects the male and female have no similarity even in form. The male of the glow-worm is a beetle, which flies in the dark, and is attracted not by the form, but the brilliancy of his mistress (σ). The female gall insect is a large mass like a vegetable

274
Different
appear-
ance of the
sexes.

(σ) Such glowing beauty allures enemies as well as lovers. "In Jamaica, in some seasons of the year, (says Dr Darwin), the fire-flies are seen in the evenings in great abundance. When they settle on the ground, the bull-frog greedily devours them; which seems to have given origin to a curious, though cruel, method of destroying these animals: If red-hot pieces of charcoal be thrown towards them in the dusk of the evening, they leap at them, and, hastily swallowing them, are burnt to death." *Botanic Garden*. From this fact the romantic moralist and spiritualizer might derive some hints for amusing declamation; and in their dissuaves might plausibly demonstrate, that in most cases beauty is fatal to the object beloved, to the lover, and destroyer.

275 **General** vegetable excrecence, without locomotion; the male a small fly full of activity. The one is as unlike to the other as a Harpy to a Venus, and as disproportioned in point of bulk as a horse to an elephant.

Male and female parts of animals. In many animals the distinctions of sex are concealed in the body. When any of their parts are placed externally, or protruded occasionally, the male parts are usually prominent, and the female hollow, in order to receive them. In the acari, however, in many flies, and a few hornets, the case is reversed; the female parts suffer erection, and the male parts are open and hollow for their reception.

276 **Their situation.** The external situation of these parts is very much varied in different animals. In many worms it is near to the head. It is often upon the side of the snail: near to the breast in the female of the dragon-fly. It is at the extremity of the antennæ in the male spider. The vulva enters from the rectum in birds. Its common situation in most animals is well known. ---The male penis, where there is one, is sometimes found to enter the vulva, and sometimes not: it is sometimes imperforated, sometimes forked, sometimes double, sometimes fleshy, sometimes bony, sometimes straight, sometimes winding spirally like a screw, sometimes with a knob and sometimes with a point at its extremity, according to the kinds and varieties of animals.

277 **Androgynous animals.** Few individuals have more than one sex. Many snails, however are androgynous, and have two. In copulation they perform the office of two sexes, and are mutually impregnated. This circumstance has often led the sensualist to wish that he were a snail. With equal reason the Epicure might wish to be one of those worms that imbibe by absorbents, and suck in nourishment by a thousand mouths. The organs employed may be more in number, the continuance of their function may be much longer, and yet the gratification may be less. The discreet beauty can afford a million of pleasures to her lover which no snail or sensualist enjoys, and which prostitution can never yield.

278 **Male and female parts of vegetables.** The male and female parts of the vegetable are sometimes both on the same flower, sometimes on separate flowers, and sometimes even on different plants of the same species. Besides the flower another organ of generation is found in vegetables. This is the corona, from which the buds and branches proceed. It is a substance between the pith and the ligneous circles, and from which the diametral insertments diverge.

279 **Parts of generation change, and sometimes disappear.** The corona is most conspicuous at the time when it sends forth shoots. The flower comes forth only at the time when the seed is to be formed; and the testicles and ovaries of those animals which procreate only at stated periods are diminished in size, and sometimes disappear, till the genial season. Even some females, when they cease to be prolific, as the pheasant, for instance, assume many marks of the other sex, as if their former sex had been assumed only for a while, and to answer some temporary purpose.

In all animals the incipient embryos are perhaps neuters, and the sex determined according to the predominancy of the male or female stimulus on the parts. It would not a little confirm this opinion, were the ob-

ervation to be well founded, that certain bulls are very apt to beget males and others females, and that certain cows which have females always when they are young bring forth males when they grow old. The different proportions of males and females in different climates might also serve to illustrate this doctrine. It is no objection to it that the order of male and female births in the same family is often irregular. The proportional force of the two stimuli will naturally be different at different times. It may depend on the quantity or quality of the fluid secreted, upon the difference of ardour in the parties, on the fancy, the passions, the particular state of the system at the time, and a thousand circumstances, besides the age, and the usual or general habit of the body. We mean only to infer at present, that wherever a male or female is produced, the stimulus of that particular sex, whatever was the cause, had during the time of coition and conception acquired the ascendancy over the parts that were to become sexual in the embryo. We cannot so readily answer the question, Why the offspring should possess the form and dispositions of one parent, and the sex of the other? In this case the different stimuli may have acted differently on different parts; in the case of hermaphrodites, which are very common in the horse, the ass, the cow, and the sheep, the two parents seem to divide the form, the sex, and the dispositions, equally between them.

The particular cause which excites the orgasmus in the female organs is not ascertained. That viscous fluid which young lascivious females eject when fond of the male, is chiefly a secretion from the glands of the vagina, the mouth of the uterus, and the neighbouring parts. In some respects it appears to be similar to those periodical discharges of females which frequently assume the erect posture; and these discharges being usually discontinued during the times of pregnancy and suckling, we must suppose that it is a portion of that fluid which nature has prepared for the use of the fetus. These discharges are always a proof that the female has arrived at the age of puberty; that her ovary is now performing its office; and that she is disposed to propagate her kind. Whatever be the cause of the female orgasmus, it is often so strong as to counteract the natural effects of the seminal fluid, and prevent impregnation. For this reason, few young and lascivious females conceive immediately after their marriage; and after coition, therefore, in cattle, it is sometimes a practice to beat the female, to plunge her in water, to weary her with running, and to use other means to prevent the return of the sexual desire.

In man, and some of the noble animals, the influence of fancy over the organs of generation is unquestionably great; but the extent and mode of its agency is not defined. Those who allow it so much power in impressing marks, and altering the form and colour of the fetus, support their opinion rather by the number than the strength of their arguments. Many of the stories which they adduce as a sort of proofs are evidently fabulous, and have brought the truth of the whole into question. The reports, however, of the French commissioners who were appointed to examine the nature of animal magnetism, ought to deter the can-

did inquire from drawing very hastily conclusions.— The queries of Frenus (H) concerning the powers of this mental faculty are important and curious, and might be of use in directing our researches; but they ought to be answered by accurate experiments, and not by acute metaphysical reasoning and historical anecdotes that are ill authenticated.

283
The mix-
ture of spe-
cies pre-
vented,
how.

To prevent a confusion of genera and species, animals are generally restricted by propensity to their own kind; and the seminal fluids, besides, being various in various animals, they cannot indiscriminately act as a stimulus on all female organs of generation. The changes of form induced by habit, which is owing itself to the influence of stimuli, will partly explain the manner in which the progeny is made to resemble the male. As the irritability of different parts is of different kinds, the stimulus will have a different effect on different organs; and in these cases where either genera or species are mixed, the parts which are most and least affected by the stimulus of the male will be obvious in the shape and form of the offspring.

284
Generation
without
sexual dis-
tinctions

We have hitherto spoken of generation as being performed by the temporary intercourse of two sexes; but the pueron is an instance where sexual distinctions are not always necessary. Even where they exist they are daily dispensed with in the vegetable kingdom. Plants grow from the gem, the bulb, the leaf, or the root — They propagate by slips, by suckers, and by layers, and some of them multiply by spontaneous separation (1). In many animals the distinctions of sex are totally unknown. It has been observed, that infusory animalcules multiply their species by continual divisions and subdivisions of their own body; that some polypes, by spontaneous separation, split transversely,

some longitudinally, and that some send off shoots. When experiments have been made upon these animals, it has been discovered that the numerous and artificial divisions of their body or their head produce entire animals. Trembley learned that they might be engrafted upon one another, and produce monsters as wild and extravagant as poet or fabulist has ever dreamed of.

Genera-
tion.

It was noticed already that the alimentary canal of some animals distributed nourishment through the whole body without the intervention of circulating vessels, and that the vital organs of vegetables were generally diffused through the whole system. The case is the same in polypes as in plants. Every part is a miniature of the whole. It is found to have similar organs of digestion, of respiration, of circulation, and of generation. In perfect animals all the parts are more dependent on one another; the vital organs have distinct situations, and their powers are concentrated in distinct places. The arm of a man has no heart; it has no lungs; it has no stomach, and no organs of generation; but the branch of a tree has as complete a system of organs as the trunk itself, and is as independent of that body from which it grew as the graft is independent of the stock.

285
Plants and
some ani-
mals con-
geries of
living bo-
dies.

The several parts of perfect animals all contribute to make one whole; the several parts of a plant or polype, when united together, form only a congeries of living bodies. These facts contribute to explain the principal phenomena in this mode of propagation.

286
Difference
between
plants and
the nobler
animals.

SECT. XIII. *Sleep.*

SLEEP is rather an affection of mind than a property of body, and is therefore more naturally a subject of metaphysics

287
Sleep.

(H) The small work of Frenus to which we allude is intitled *De Viribus Imaginationis Tractatus*. The following questions serve to give an idea of its contents, and are named *Index Questionum hujus Libri*.

Questio. I. An anima habeat vim agendi in ullum corpus?

II. In quæ corpora agere possit, et qua actione?

III. Per quas potentias illos motus et actiones exerceat?

IV. An anima agat aliquid per potentiam imaginativam?

V. An phantasia possit ullum corpus movere localiter?

VI. An possit alterare?

VII. An phantasia possit vim nullam acquirere ab influxu cælorum?

VIII. An ergo phantasia nullam habeat vim agendi?

IX. Per quas potentias phantasia corpora immutet?

X. Quid possit in corpus proprium, et specialiter, an possit in eo creare morbos?

XI. An possit morbos creare?

XII. Quid possit in alienum externum?

XIII. Quid possit in alienum propinquum seu fœtum?

XIV. Quomodo et qua ratione fœtum immutet?

XV. Quomodo possit conformatricem dirigere?

XVI. Quenam imaginatio habeat illam signandi potestatem? quæ non?

XVII. Cur non omnis imaginatio quam animi passiones sequuntur signat?

XVIII. An omnes animi passiones signant?

XIX. Quenam imaginatio signet, an tantum matris an etiam patris?

XX. An etiam brutorum imaginatio signet?

XXIV. Cur non eidem semper parti sed diversis notæ inducuntur?

(1) As the house leek and some grasses.

Sleep. metaphysics than of physiology. This affection is often induced by fatigue and exercise; and several persons, when they are weary and no longer able to move their limbs, say they are exhausted. Though the word *exhausted*, in this expression, has seldom any precise meaning, it seems, however, to have been the means of suggesting a theory with regard to sleep. This theory supposes that sleep is occasioned by the exhaustion of irritability in the living system; but it seems to be founded on very limited and partial observations, or rather has been formed, like a great many others, prior to any observations at all, and afterwards tortured to account for facts which it does not comprehend. It does not account for the periodical returns of sleep, for the almost unremitting drowsiness of infants, and for that listless lethargic inaction so often attendant on old age. When no exhaustion of irritability can well be supposed to have taken place, the propensity to sleep on many occasions becomes irresistible, from the effects of monotonous speaking, from stillness, darkness, or from the sameness of scenery around us; and when one stimulus, after long application, can rouse no more (a plain proof that the irritable principle is by no means exhausted) another stimulus that is less powerful in ordinary cases is accompanied with excitement.

288
An affection of mind.

289
Favours nutrition

Of these phenomena, we frankly confess that we can assign no physical cause that is satisfactory. It is easy, however, to see the intention which nature has in view by inducing sleep. It has long been observed, that in all living bodies there is a continual waste and repair, or, to speak with more precision and accuracy, one process of assimilation and another of dissolution constantly taking place in all the different parts of the system. It is also true that this assimilation, when the body is healthy, predominates in youth; that dissolution prevails in old age; and that the two are nearly on a par during the vigour and meridian of life. Another fact which admits of demonstration is, that a gentle and moderate exertion of mind and body will promote both. And lastly, it is certain that immoderate exertion in either respect, or any exertion that is not suited to our strength, habits, or period of life, prevents assimilation, hinders dissolution; and that the means which nature employs to restore the balance is usually by inducing a state of sleep.

290
Sleeping and waking each suited to different functions in the system.

When the balance is restored, and all the parts are again repaired for discharging their office, man awakes; but his waking period is of short duration. If appetite or passion do not engage him in some pursuit, if his mind be not occupied with some object, or if no stimuli be applied from without. This period seems chiefly intended for collecting food, and for being employed in those exertions which promote respiration, digestion, absorption, circulation, and secretion; while sleep after the food is collected, assists nutrition, and promotes assimilation throughout the system. If what is the natural food of the species cannot be collected by the plant or animal in a short time, the period of sleep is proportionally restricted. If the food received be difficultly assimilated, the period of sleep is proportionally extended. If the food be not prepared for assimilation, the sleep is disturbed. If it be difficultly prepared by the organs, the active exertions are more vigorous; if easily prepared, they are more feeble. If

it be collected during the day, the sleep is in the night; if collected in the night, the sleep takes place during the day; and all living bodies are directed by nature to select that time and species of food which is most suited to their nature, their habits, their circumstances, and age.

To favour nutrition, not only the body, but even the mind, must be allowed to indulge in rest. The child sleeps, and his mental faculties are under restraint, that those functions employed in nutrition may not be disturbed. The mental faculties are still feeble in a more advanced period of life; and the moderate exertions of mind and body which are natural to youth are chiefly such as favour the preparatory organs of the system, and promote growth: but the active and vigorous exertions of manhood, considered with respect to mind or to body, soon cause dissolution to preponderate in the scale, and old age becomes listless, inactive, and drowsy, and the mind returns to childhood or dotage, because living bodies are known to accommodate themselves to circumstances, and because the prevailing dissolution is retarded by the frequent returns of rest and of sleep, which favour so much the assimilating powers, counteract *re-absorption*, and oppose decay.

During sleep the irritable principle is more languid, and all the senses are more obtuse. The mind then is withdrawn to its rest, and does not attend to stimuli from without. The same happens when the mind is absorbed in profound thought: but profound thought is hurtful to the system. The mind then is engaged in pursuits peculiarly its own, and is less attentive to the calls of nature. In the time of sleep it withdraws seemingly, not so much for its own sake as that of the body, which then being freed from the interruption of voluntary motions, all those organs which act spontaneously can more easily discharge their functions.

For the best of reasons, the mind is not allowed to judge for itself when it is proper to eat, to drink, to sleep, to wake, and to propagate the species. These and the like are offices too important to be wholly intrusted with a being of so very limited intelligence. In all these cases, it is therefore directed by certain propensities resulting from the body in consequence of stimuli or organic structure. Being often amused with thoughts and ideas on those objects which are purely intellectual, as the notes of memory, the forms of fancy, and its own operations in the way of reasoning; being invested with some little power in rousing, calming, and regulating the passions, the desires, and appetites; and having the command of all the voluntary movements of the body; it sometimes neglects its charge of the system, destroys it sometimes by excessive indulgence, and sometimes employs it in accomplishing ends peculiarly its own. One should imagine that the mental principle in the lower animals should occasion but little disturbance to the system; yet it has been observed that geese fatten sooner in the dark than they do in light, where the mind is entertained with varieties of objects; and this circumstance will partly explain why man does not fatten so regularly as the brute, and why castration, which prevents so much anxiety and passion and exhausting efforts, assists growth and the organs of nutrition. The venereal stimulus, for this reason, is not strongly felt at a very early period of youth, nor is very troublesome in old age. In the former case it would

Sleep.
291
Violent exertions of mind or body hurtful to the system.

292
Mental exertion counteracts nutrition.

293
Charge of the system not contracted by the mind, therefore

would

294
The system accommodates with respect to sleep.

would prevent the growth of the system; in the latter it would hasten its dissolution.

The natural returns of waking and sleeping may be altered by the presence or absence of stimuli, and are curiously affected by the influence of habit. Although the commencement of one of these periods happen to be changed, the commencement of the other will continue as before. If a person be accustomed to sleep precisely at nine in the evening, and to rise again at six in the morning, though his sleep in the evening may now and then be kept off till twelve, he will waken at six; and though continued by darkness, quietness, or such like causes, till the day be advanced, it will recommence in the evening at nine. The state of physiology is such at present that we cannot assign any precise physical cause for the natural kinds of sleeping and waking, or for their regular periods of return. As for the causes which occasion morbid sleeping and waking, we refer our readers to books on pathology.

295
Sleep of plants.

Plants too have been said to sleep. At the approach of night, many of them are observed to change their appearances very considerably, and sometimes even to such a degree as scarcely to be known for what they were before. These changes happen principally to the leaves and the flowers. During the night, many leaves, according to the nature and genus of the plant, are seen to rise up, to hang down, or to fold themselves in various ways for the protection of the flowers, the buds, the fruits, or young stems; and many flowers, to escape a superabundance of moisture, to hang down their mouths towards the earth, or wrap themselves up in their calices. It was mentioned already, that these phenomena are owing to stimuli acting from without: we may add here, that most of the motions are performed at the joints where the leaves and petals articulate with the stem. A period of rest is as necessary to plants as sleep is to animals. The irritable principle cannot act long under the influence of the same stimulant, except at intervals; and the rapid growth observable in plants during the night, is a strong proof that the organs employed in assimilation had been disturbed in discharging their functions during the day, when exposed to the actions of heat and light and of other stimulants.

SECT. XIV. *Death.*

296
Death.

DEATH is the cessation and total absence of the living principle in organized bodies. It is sometimes imitated by sleep and swoons; and a state of torpor in many instances can hardly be distinguished from it. Several moles and a few animals, as the ears of blight-

ed wheat, the seta equina, the wheel polype, and some snails as we learn from the Philosophical Transactions, may be safely preserved as dried preparations, not for months only but for years; and after irritability and sensation have been totally suspended, will return to life upon the proper application of moisture. A wheel polype was put by Fontana upon a bit of glass, and exposed during the whole summer to the noontday sun; another was exposed in a similar manner for a year and a half; and after they were like a piece of hardened glue, were restored to the use of all their functions by a few drops of water (κ). Wherever there is death, there must therefore be likewise a partial or general decomposition of one or more of the vital organs. This decomposition takes place naturally in some living bodies after a few hours, in some after a few days; the life of others is extended to weeks, some are vigorous for months or a season. Man has often seen more than fourscore; and the hardy oak survives the shock of two or three centuries. These observations conspire to show that there is a certain period of existence allotted by nature to every species of living bodies. In the individual this period is sometimes abridged, and may be sometimes extended by circumstances; but yet there is a bound which it cannot pass, when the vital organs must be decomposed, and the system return to moulder with the dust. The time of incubation and the time of gestation are pretty much desired in every species, because the circumstances of the individual in these cases are generally similar; but after emerging from the fetal state, the individuals are partly entrusted to their own organs and the chances of life, which are much varied; and hence we account for the difference of their age.

Life in general seems to be proportioned to the space occupied by that series of functions which the species is evidently destined to perform; and here sometimes the accommodating principle is singularly remarkable. As the period of decay is never seen to commence in the species till that of propagation be nearly elapsed, and as propagation in the lower tribes of plants and of animals is often the immediate harbinger of death; so many animals which have not propagated, indulged the propensity, nor became uneasy from the languor of desire, continue vigorous longer than ordinary, as if it were waiting for an opportunity to multiply their kind. And in the vegetable kingdom, where no individual is ever the victim of desire or passion, annuals, if prevented from flowering and seeding in their proper season, will live double, and sometimes triple, the usual time, till these functions

Death.
297
In some instances not distinguishable from a state of torpor.

298
A certain period of life allotted to the species.

299
Accommodates with respect to individuals.

300
Life proportioned to the series of functions to be performed.

(κ) Father Gumillo a Jesuit, and the Indians of Peru, says Dr Fowler, are quoted by Fontana, on the authority of Bouguer, as speaking of a large and venomous snake, which being dead and dried in the open air or in the smoke of a chimney, has the property of coming again to life on its being exposed for some days to the sun in stagnant and corrupted water. But, adds the Doctor, it would almost require the credulity of an Indian to credit the testimony of the Jesuit. *Experiments and Observations relative to Animal Electricity, by Richard Fowler.*—With regard to this report, we shall only observe, that the snake would not readily return to life after it was dead; but if the Jesuit meant only that it recovered after it was dried, and its several functions had been suspended, we must say, that if his report be not sufficiently authenticated, neither has it been sufficiently disproved.

Death. be somehow performed, and then die. But when all the organs are fully evolved and have discharged, or have continued for the usual time capable of discharging, those offices for which they were intended ; dissolution commences, the assimilating organs begin gradually to lose their tone, and the reabsorbents carry off more from the different parts than what they receive in the way of nutrition : the irritable fibre then becomes rigid ; the membranes and cartilages begin to ossify ; the bones grow harder ; the smaller vessels collapse and disappear ; the parts no longer are obedient, as before, to the action of stimulants ; and death ensues.

301 Symptoms of decay.

Some, in order to account for this event, imagine that the body receives at first a certain portion of irri-

tability, and continues to live till that be exhausted: but this theory explains nothing ; and without pretending to a great deal of foresight, we will venture to predict, that for all the irritability which it has, it will not be distinguished for its longevity.

With regard to the periods by which the life, the functions, and diseases of living bodies are so frequently regulated, and which periods may sometimes be varied but not evaded, the most prudent language that, perhaps, can be adopted in the present state of physiological science is this of the Divine, That the God who formed us hath numbered our days, determined our times, and prescribed the limits of our existence.

Death. 302 An attempt to account for death. 303 Physical causes not easily assigned for periodical phenomena in the system.

The following TABLE may be considered as in some respect a summary view of the foregoing Sections, and as a Supplement to the Table of D'Azyr.

I. RESPIRATION.	Some living bodies have respiratory organs (L)	<ul style="list-style-type: none"> Diffused through the system. Confined to one place. Situated externally. Situated internally. In the course of circulation. Not in the course of circulation. Within or without the course of circulation at pleasure. Without tracheæ (M). With tracheæ ramified through the system where the respiratory organs are generally diffused. ————not ramified through the system where the respiratory organs are confined. ————formed by rings. ————by segments of rings on one side, and a membrane on the other. ————by continuous rings running spirally like a screw. ————admitting air by one entrance. ————by several entrances. ————wholly concealed in the body. ————partly projecting from the body. ————opening at the head. ————at the opposite extremity. ————upon one side. ————upon both sides.
2. DIGESTION.	Some living bodies have alimentary canal	<ul style="list-style-type: none"> Without teeth. With teeth in the mouth. ———— in the stomach. ———— stones or artificial teeth in the stomach. ———— glands in the mouth for secreting a liquor to be mixed with the food. ———— pouches in the mouth where the food is kept and moistened. ———— a sac or bag where the food is kept and moistened. ———— a membranous stomach. ———— a muscular stomach. ———— an intermediate stomach. Without a cœcum or blind gut. With a cœcum. } These parts, as well as ———— two cœca. } ruminating stomachs and ———— three cœca. } their œsophagus, have an- ———— four cœca. } tiperistaltic motions. ———— one entrance or mouth. ———— many entrances by absorbents.

Plants

(L) The gentlemen of the French Academy, who have been attentive to mark the number of lobes in the lungs and livers of different animals, have sufficiently demonstrated, by the facts which they relate, that many of these physiological conclusions which have been drawn from the number of lobes in these two viscera, are just as delusive as many of those which have been drawn from the number of lobes and the different tubercles found in the brain.

(M) Where the respiratory organs are situated externally.

3. DIGESTION. } Plants have many alimentary canals (n).
 } Some polypes have alimentary canals that branch through the body.
 } The alimentary canals of plants, of some polypes, and worms, distribute the fluids without the aid of a circulating system.

3. ABSORPTION. } Performed { By vessels beginning from the alimentary canal.
 } Performed { _____ from the cavities.
 } Performed { _____ from the surface.
 } Performed { — veins in the penis and placenta.
 } Performed { — reabsorbents originating from all the parts of the system.

4. CIRCULATION. } Some living bodies have { No circulating system.
 } Some living bodies have { A circulating system with one heart.
 } Some living bodies have { _____ a heart for distributing the blood through the respiratory organs, and an artery for distributing it through the system.
 } Some living bodies have { _____ one heart for the respiratory organs, and one for the system, both in one capsule.
 } Some living bodies have { _____ two hearts for the respiratory organs, and one for the system.
 } Some living bodies have { _____ a pulmonary heart, or a heart for the respiratory organs in the course of circulation.
 } Some living bodies have { _____ a pulmonary heart within or without the course of circulation at pleasure.
 } Some living bodies have { _____ a heart situated in the breast.
 } Some living bodies have { _____ near to the head.
 } Some living bodies have { _____ in the opposite extremity.

5. NUTRITION. } The food is prepared. { By the alimentary canal.
 } The food is prepared. { — the lacteals.
 } The food is prepared. { — the respiratory organs.
 } The food is prepared. { — the circulating system.
 } The food is prepared. { — the cellular membrane.
 } The food is prepared. { — glands.
 } The food is prepared. { And by the several parts in which it becomes finally assimilated.

6. SECRETION. } Performed { By vessels.
 } Performed { — exhaling vessels.
 } Performed { — excretory organs.
 } Performed { — organic pores.
 } Performed { — glands.
 } Performed { And by all the parts of which the system is composed.

7. INTEGUMENTATION (o). } Some living bodies have integuments. { Which are scaly.
 } Some living bodies have integuments. { _____ shelly.
 } Some living bodies have integuments. { _____ membranous.
 } Some living bodies have integuments. { _____ corneous.
 } Some living bodies have integuments. { _____ cretaceous.
 } Some living bodies have integuments. { _____ ligneous.
 } Some living bodies have integuments. { _____ covered with down.
 } Some living bodies have integuments. { _____ hair.
 } Some living bodies have integuments. { _____ prickles.
 } Some living bodies have integuments. { _____ feathers.
 } Some living bodies have integuments. { _____ a viscid matter.
 } Some living bodies have integuments. { _____ change their colour.
 } Some living bodies have integuments. { _____ their covering.
 } Some living bodies have integuments. { _____ are changed themselves.

8. IRRIGATION.

(n) The subterraneous bulbs, the swollen fleshy parts of the roots, and certain cups and vesicles which contain water, serve often as reservoirs of food to the plants, although for various reasons we have not ventured to call them stomachs. *Stomach* would be a vague and unmeaning word were it applied even to all these reservoirs of water or secreted fluids which we find in fishes, and by which some of these animals are preserved alive on the dry shore till the tide return.

(o) There seems to be a want of precision in classing bones with integuments, or integuments with bones, as

3. IRRITABILITY. }
 The irritable principle }
 effected. }
 — By stimulants invisible.
 — ——— unknown.
 — ——— unthought of.
 — the nervous influence.
 — light.
 — heat.
 — moisture.
 — electricity.
 — salts.
 — gases.
 — bodies that act mechanically.

9. MOTION }
 Locomotion performed }
 — By legs.
 — wings.
 — fins.
 — the tail.
 — organs which fall not properly under these descriptions.
 — the springiness of the body or of some part of it.
 — contrivances which fit living bodies for being moved by foreign agents (P).

is done in D'Azyr's table. Comparatively speaking, bones are confined to a few genera of living bodies, and are never subject to periodical changes like the integuments or cuticular coat of the alimentary canal in some animals.

For the sake of perspicuity, it could have been wished that either anatomists or physiologists had defined bones in a manner different from what they have done, and as far as possible avoided those loose and inaccurate expressions which disgrace science; for some speak of animals having their bones, by which they mean shells, on their outside, and the muscles within them. Some speak of solid and compact bones, that were once cartilages, membranes, nay a mere jelly; and some speak of bones in general as the hardest, most solid, and most inflexible parts of the organized body. From all this we are led to infer, that integuments, if hard, solid, and inflexible, may be called bones; that the heart and blood-vessels, if converted into a hard, solid, and inflexible substance, may be called bones; and that a jelly, a membrane, or a cartilage, if it can be supposed that in the course of nature they will become hard, solid, and inflexible, may likewise be called bones. But certainly if hardness, solidity, and inflexibility, be to constitute the characteristics of bones in a living body, however often we may be necessitated to include shells, wood, horns, and stony concretions, under that denomination, we can never with propriety speak of bones that are cartilaginous, membranous, or even a mere jelly. These expressions might be proper enough were ossification considered merely as a natural or accidental circumstance, and were bones defined to be those internal parts of an animal which are intended by nature to form what is meant by the skeleton in its usual sense. These parts, we know, after passing through the forms of jellies, membranes, and cartilages, often become hard, solid, and inflexible, from ossification; a species of induration which is natural to the parts which form the skeleton of some animals, an induration which occasionally is extended to other parts, which sometimes exhibits the appearance of crystallization, and in many respects is different from the manner in which the wood of vegetables and the shells of animals become hard.

Ossification does not interfere so much as may be commonly imagined with the structure of bones: the structure of bodies may often be similar, and yet their mode of induration be different. Bones have been observed to consist of laminæ, or plates like shells, and cylindric bones of concentric circles like wood. The concentric circles of wood have been found to consist of indurated membranes, which they receive successively from the bark; and Swammerdam discovered that the shells of some fishes were composed of laminæ that consisted likewise of indurated membranes or hardened cuticles, that had been successively furnished by the body. It has thence been supposed that bones, though hardened in a different manner, are of a structure nearly similar to that of some ligneous bodies and shells, and that their laminæ in many instances consist also of indurated membranes, supplied successively by the periosteum when it is present. When it is absent, nature, which accommodates herself to circumstances, can form the bone in another way, and afterwards cover her new productions with a periosteum. For many excellent physiological observations on bones, we refer our readers to the *Osteology* of the late Dr Monro, and particularly to the volume already published of Mr Bell's *System of Anatomy*.

(P) The pulp which surrounds seeds is often the means of their propagation. Animals swallow the seeds for the sake of the pulp; and the seeds remaining indigestible, are carried to a distance, and discharged with the feces.

10. HABIT.	Accommodates with respect	<ul style="list-style-type: none"> To respiration. — digestion. — absorption. — circulation. — nutrition. — secretion. — integumentation. — irritability. — motion. — transformation. — generation. — sleep. — death. — form. — size. — climate. — propensity. — the healing of parts that are morbid. — the renewal of those that are broken off.
11. TRANSFORMATION.	Takes place	<ul style="list-style-type: none"> By a change of proportion among the parts. — of their form. — throwing off old parts. — an addition of new ones of a different use, structure, and form. — a change of the whole form together. — of qualities, propensities, manners.
12. GENERATION.	Performed	<ul style="list-style-type: none"> By the temporary union of two sexes. — the spontaneous separation of parts. — organs situated in the breast. — in the side. — near to the head. — in the opposite extremity. — an intransient organ of the male and a recipient organ of the female. — an intransient organ of the female and a recipient organ of the male. — the stamens and pistils of flowers. — the femoral secretion of the male thrown into the organs of the female. — sprinkled at the entrance of the female organs. — thrown upon them from a distance. — transported to them by the winds. — sprinkled on the embryo after emission. — dissolved in a fluid secreted by the female before it can rightly perform its office. — dissolved in water. — dissolved perhaps sometimes in air, as in the case of diœcous plants, where it probably acts like an aroma.
13. SLEEP.	Natural sleep is occasioned	<ul style="list-style-type: none"> By quietness. — the absence of stimuli. — the sameness of stimuli when long continued. — deficient assimilation. — deficient irritability, which is owing sometimes to the weakness, inattention, or confined powers of the mental principle.
14. DEATH.	Happens naturally to some species of living bodies	<ul style="list-style-type: none"> After hours. — days. — weeks. — months. — seasons. — years. Not till after centuries.

All living bodies are much exhausted after performing the act of generation, and many of the inferior plants and animals begin immediately to sicken and decay.

We conclude by confessing, that concerning many uses of the parts, and concerning different species of variety in the form, structure, and position of the organs, much, after all, is still reserved for farther reading, for farther observation, and for future physiological arrangement.

P I A

P I A

Phytolacca PHYTOLACCA, **POKEWEED**, or *American nightshade*, in botany, is of the decandria icofandria class of plants. It grows naturally in the United States of America. It hath a thick, fleshy, perennial root, divided into several parts as large as middling parsneps. From this rise many purplish, herbaceous stalks, about an inch thick, and six or seven feet long, which break into many branches, irregularly set with large, oval, sharp-pointed leaves, supported on short footstalks. These at first are of a fresh green colour, but as they grow old they turn reddish. At the joints and divisions of the branches come forth long bunches of small bluish coloured flowers, consisting of five concave petals each, surrounding ten stamina and ten styles. These are succeeded by round depressed berries, having ten cells, each of which contains a single smooth seed.

Piacenza.
Bryant's
Flora Dietetica.

Piacenza
Puffin

In Virginia and other parts of America the inhabitants boil the young leaves, and eat them in the manner of spinach. They are said to have an anodyne quality, and the juice of the root is emetic and cathartic. The young stems when boiled are as good as asparagus; but when old they are to be used with great caution, being violently cathartic. The Portuguese had formerly a custom of mixing the juice of the berries with their red wines, in order to give them a deeper colour; but as it was found to debase the flavour and to make the wine deleterious, the matter was represented to his Portuguese Majesty, who ordered all the stems to be cut down yearly before they produced flowers, thereby to prevent any further adulteration. The same practice was common in France till it was prohibited by an edict of Louis XVI. and his predecessor under pain of death. This plant has been said to cure cancers; but the truth of this assertion requires to be proved by a greater number of experiments. Dr Shultz in his ingenious inaugural dissertation on this subject observes that "scabies and herpes have been often removed by it. In these cases, a solution of the extract in water is generally substituted, where the expressed juice cannot be had.—In rheumatism the whole substance of this plant has at different times been of essential service; although the berries have generally been preferred. In those rheumatic affections which sometimes occur to syphilitic patients, its virtue far exceeds that of opium."

For medical purposes "the leaves should be gathered about July, (when the foot-stalks begin to assume a reddish colour), dried in the shade and powdered for use. An extract may easily be obtained from the leaves when gathered at this period, by gently evaporating their expressed juice to a proper consistence.

"A tincture may be made by dissolving either the extract, or the leaves, in their green or dry state in common brandy; or in the spirit distilled from the berries.

"An ointment is also made by powdering the dried leaves, and mixing them well with hogs lard, or simple cerate; or by boiling some hogs lard and bees-wax with fresh leaves, and straining the mass. The proper

time for gathering the berries in this climate, will be in October, when they become soft and ripe, and are of a blackish colour. They are generally used in tincture, made by infusing them in Brandy. An extract may easily be made by evaporating their expressed juice.

"The root is to be gathered about November or December, when the stalks of the plant are perfectly dead. It may be prepared in the same manner as the leaves are; but to facilitate drying, it should be perfectly divided into small pieces." It has also been used in compounds as an article in dyeing.

PHYTOLOGY, a discourse concerning the kinds and virtues of plants. See **BOTANY**, and **MATERIA Medica**.

PHYTON, a general of the people of Rhegium against Dionysius, the tyrant of Sicily. He was taken by the enemy, and tortured, and his son was thrown into the sea. See **SYRACUSE**.

PIA MATER. See **ANATOMY**, n^o 130. p. 756, &c.

PIABA, in ichthyology, is a small fresh-water fish, caught in all the rivers and brooks in the Brasils, and in some other parts in America. It is about the bigness of the common minnow; is well tasted, and much esteemed by the natives.

PIABUCU, in ichthyology, is an American fish eaten in many places by the natives. It is ravenous, and so greedy of blood, that if a person goes into the water with a wound in any part of his body, the piabucu will make up to it to suck the blood. It seldom exceeds four inches in length.

PIACENZA is a city of Italy, in the duchy of Parma, in E. Long. 10. 25. N. Lat. 45. It is a large handsome city, whose name is derived by some from its pleasant situation, in a fruitful plain, on the Via Emilia, about half a mile from the Po. It is the see of a bishop suffragan of Bologna, and has a university, but of no great fame. It is defended by a wall and a strong citadel, and is reckoned about three miles in circumference, so that it is somewhat bigger than Parma.

PIASTUS, a native of Poland, was originally a wheelwright and the son of Cossico, a citizen of Crufwitz. He flourished in the year 830, when on the extinction of the family of Popiel great disputes arose about his successor, and Cracow was afflicted with a severe famine. During this extremity, when the people were dropping down in the streets, two angels in human forms, as the story is told, took up their residence with Piastus, who was celebrated for his piety and extensive charity. He had nothing left but a small cask of the common liquor of the country, and this he presented to his new guests, who charmed with his hospitality, promised him the crown of Poland. The faith of Piastus was equal to his other virtues: he implicitly believed the word of his guests, and piously followed their directions in every particular. He was ordered to distribute the liquor out of his little cask to the multitude: he did so, and found that it was inexhaustible. The people were astonished; all cried out,

Piaſtus
↑
P'broch.

"A miracle!" and the electors determined to chuſe a perſon in whoſe favour Heaven had ſo viſibly declared: Piaſtus was accordingly taken from his ſhop, and raiſed to the ducal dignity.

Such is the relation of the canon of Cracow, which differs in many particulars from the account given by Guagnini and ſeveral other hiſtorians. According to them, Piaſtus had prepared a ſmall collation, to entertain ſome friends who were aſſembled at the birth of a child. Two pilgrims, Paul and John, afterwards murdered at Rome, came about this time to Cracow. They begged charity at the door of the election-hall, and were rudely repulſed; upon which they ſtumbled on the houſe of Piaſtus, and were kindly received. The miracle we have mentioned was wrought by them; and the two pilgrims, and not angels, were the inſtruments of the elevation of the hoſpitable wheelwright. Tho' we pay but little regard to the marvellous means by which Piaſtus aſcended the ducal throne of Poland, it would be preſumptuous entirely to omit a fact attested by all the writers upon this ſubject: it was proper, therefore, to take notice of it, and we leave the reſt to the reader's judgment.

Being now raiſed to the ſupreme dignity, he was not intoxicated with his proſperity. His natural charity, benevolence, and ſweetneſs of diſpoſition, remained: nothing was altered but his power of doing good. He was truly called the father of his people: the injured never returned unredreſſed, nor merit unrewarded. Piaſtus wiped the tear from the eyes of the widow: and was himſelf the guardian of the orphan, and the general patron of the poor and diſtreſſed. His excellent inclinations ſerved him in the room of great abilities; and the happineſs that his people enjoyed made them forget that their prince was not born a ſtateſman and a warrior. Several inſtinctive commotions aroſe during his adminiſtration, all which he quelled by the mildneſs and clemency of his nature: his nobility were aſhamed of rebelling againſt a ſovereign who devoted his whole life to render his people happy. He removed the court from Crufwitz, a city which he deteſted, becauſe it was the ſcene of Popiel's crimes and tragical end, and fixed his reſidence at Gneſna, where he died beloved, eſteemed, and even adored by his ſubjects.

It is in memory of this excellent prince, that all the natives of Poland, who have been ſince promoted to the ducal or regal dignity, were called Piaſtes, in contradiſtinction to the foreigners.

Piaſtus aſſociated his ſon Ziemovitus with him in the government before his death; a circumſtance of much benefit to the people.

PIAZZA, in building, popularly called *piache*, an Italian name for a portico, or covered walk, ſupported by arches.

The word literally ſignifies a broad open place or ſquare; whence it alſo became applied to the walks or porticoes around them.

* I ſays by
Dr Beattie,
3. to edit.
P. 422.
note.

PIBROCH, ſays Dr Beattie *, is a ſpecies of tune peculiar, I think, to the Highlands and Weſtern Iſles of Scotland. It is performed on a bagpipe, and differs totally from all other muſic. Its rythm is ſo irregular, and its notes, eſpecially in the quick movement, ſo mixed and huddled together, that a ſtranger finds it almoſt impoſſible to reconcile his ear to it, ſo as to

perceive its modulation. Some of theſe pibrochs, being intended to repreſent a battle, begin with a grave motion reſembling a march, then gradually quicken into the onſet; run off with noiſy confuſion and turbulent rapidity, to imitate the conflict and purſuit; then ſwell into a few flouriſhes of triumphant joy; and perhaps cloſe with the wild and flow wailings of a funeral proceſſion.

PICA, in ornithology. See CORVUS, ſp. 9.

PICA *marina* in ornithology. See HÆMATOPUS, and ALCA, n^o 3.

PICA, in medicine, a depravation of appetite, which makes the patient long for what is unfit for food, or incapable of nouriſhing; as chalk, aſhes, coals, plaſter-lime, &c. See MEDICINE, n^o 371.

PICA, or *pye*, had formerly the ſame ſenſe as *ordinal*, meaning a table or directory, pointing out the order in which the devotional ſervices appointed for different occaſions were to be performed. Accordingly we are told it is derived from π, a contraction of πναξ, a table: and by others from *litera picata*, a great black letter at the beginning of ſome new order in the prayer. The term was uſed in a ſimilar ſenſe by officers of civil courts, who called their kalendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts the *pyes*.

PICARD, a native of the Netherlands, who founded a ſect the profeſſors of which were called *Picards*. See PICARDS.

PICARD (John), an able mathematician, and one of the moſt learned aſtronomers of the 17th century, was born at Fleche, and became prieſt and prior of Rillie in Anjou. Going to Paris, he was in 1666 received into the Academy of Sciences in quality of aſtronomer. In 1671, he was ſent, by order of the king, to the caſtle of Uraniburg, built by Tycho Brahe in Denmark, to make aſtronomical obſervations there; and from thence he brought the original manuſcripts wrote by Tycho Brahe, which are the more valuable as they differ in many places from the printed copies, and contain a book more than has yet appeared. He made important diſcoveries in aſtronomy; and was the firſt who travelled through ſeveral parts of France, to meaſure a degree of the meridian. His works are, 1. A treatiſe on levelling. 2. Fragments of dioptrics. 3. *Experimenta circa aquas effluentes*. 4. *De menſuris*. 5. *De menſura liquidorum & aridorum*. 6. A voyage to Uraniburg, or aſtronomical obſervations made in Denmark. 7. Aſtronomical obſervations made in ſeveral parts of France, &c. Theſe, and ſome other of his works, which are much eſteemed, are in the ſixth and ſeventh volumes of the Memoirs of the Academy of Sciences.

PICARDS, a religious ſect which aroſe in Bohemia in the 15th century.

Picard, the author of this ſect, from whom it derived its name, drew after him, as has been generally ſaid, a number of men and women, pretending he would reſtore them to the primitive ſtate of innocence wherein man was created: and accordingly he aſſumed the title of the *New Adam*. With this pretence he taught his followers to give themſelves up to all impurity; ſaying that therein conſiſted the liberty of the ſons of God; and that all thoſe not of their ſect were in bondage.

He

Pica
↑
Picards.

Picards. He first published his notions in Germany and the low countries, and persuaded many people to go naked, and gave them the name of *Adamites*. After this he seized on an island in the river Lausnitz, some leagues from Thabor, the head quarters of Zisca, where he fixed himself and his followers. His women were common, but none were allowed to enjoy them without his permission: so that when any man desired a particular woman, he carried her to Picard, who gave him leave in these words, *Go, increase, multiply, and fill the earth.*

At length, however, Zisca, general of the Hussites, (famous for his victories over the emperor Sigismund), hurt at their abominations, marched against them, made himself master of their island, and put them all to death except two; whom he spared, that he might learn their doctrine.

Such is the account which various writers, relying on the authorities of Æneas Sylvius and Varillas, have given of the Picards, who appear to have been a party of the Vaudois, that fled from persecution in their own country, and sought refuge in Bohemia. It is indeed doubtful whether a sect of this denomination, chargeable with such wild principles and such licentious conduct, ever existed; and it is certainly astonishing that Mr Bayle, in his art. *Picards*, should adopt the reproachful representations of the writers just mentioned: for it appears probable at least that the whole is a calumny invented and propagated in order to disgrace the Picards, merely because they deserted the communion and protested against the errors of the church of Rome. Lasitius informs us, that Picard, together with 40 other persons, besides women and children, settled in Bohemia in the year 1418. Balbinus the Jesuit, in his *Epitome Rerum Bohemicarum*, lib. ii. gives a similar account, and charges on the Picards none of the extravagancies or crimes ascribed to them by Sylvius. Schlecta, secretary of Ladislaus, king of Bohemia, in his letters to Erasmus in which he gives a particular account of the Picards, says that they considered the pope, cardinals, and bishops of Rome, as the true Antichrists, and the adorers of the consecrated elements in the eucharist as downright idolaters; that they denied the corporal presence of Christ in this ordinance; that they condemned the worship of saints, prayers for the dead, auricular confession, the penance imposed by priests, the feasts and vigils observed in the Romish church; and that they confined themselves to the observance of the sabbath, and of the two great feasts of Christmas and Pentecost. From this account it would appear that they were no other than the Vaudois; and M. de Beaufoire has shown that they were both of the same sect, though under different denominations. Besides, it is certain that the Vaudois were settled in Bohemia in the year 1178, where some of them adopted the rites of the Greek, and others those of the Latin church. The former were pretty generally adhered to till the middle

of the 14th century, when the establishment of the Latin rites caused great disturbance. On the commencement of the national troubles in Bohemia, on account of the opposition to the papal power (see *MORAVIANS*), the Picards more publicly avowed and defended their religious opinions; and they formed a considerable body in an island by the river Lausnitz or Lausnitz, in the district of Bechin, and recurring to arms, were defeated by Zisca. *Ency. lep.* art. Picards.

PICARDY, a province in France, is bounded on the north by Hainault, Artois, and the Straits of Calais; on the east by Champagne; on the south by the Isle of France; and on the west by Normandy and the English Channel (A). This province is long and narrow, being usually compared to a bent arm; and in this figure is nearly 150 miles in length, but not above 40 in breadth, and in many places not above 20. It is generally a level country; and produces wine, fruit of all kinds, plenty of corn, and great quantities of hay: but wood being scarce, most of the inhabitants burn turf. They have, however, some pit-coal, but it is not so good as that of England. It was united to the crown of France in the year 1643; and is supposed to contain 533,000 inhabitants.

Its principal rivers are the Somme, the Oise, the Canche, the Lanthie, the Lys, the Aa, the Scarpe, and the Deule.

The situation of this province on the sea, its many navigable rivers and canals, with the industry of the inhabitants, render it the seat of a flourishing trade. In it are made beautiful silk stuffs, woollen stuffs, coarse linen, lawn, and soap; it also carries on a large trade in corn and pit-coal. In the government of Calais and Boulogne are annually bred 5000 or 6000 colts, which being afterwards turned loose in the pastures of Normandy, are sold for Norman horses. The fisheries on this coast are also very advantageous. This province is divided into Upper, Middle, and Lower Picardy; and is again subdivided into four deputy-governments. The principal town is Amiens.

PICART (Bernard), a celebrated engraver, son of Stephen Picart, also a famous engraver, was born at Paris in 1673. He learned the elements of his art from his father, and studied architecture and perspective under Sebastian le Clerc. As he embraced the reformed religion, he settled in Holland to enjoy the free exercise of it; where his genius produced those masterpieces which made him esteemed the most ingenious artist of his age. A multitude of books are embellished with plates of his engraving. He died in 1733.

PICCOLOMINI (Alexander), archbishop of Patras, and a native of Sienna, where he was born about the year 1508, was of an illustrious and ancient family, which came originally from Rome, but afterwards settled at Sienna. He composed with success for the theatre; but he was not more distinguished by his genius, than by the purity of his manners, and his regard to virtue. His charity was very great; and was chiefly

Picardy

ii. 454.

(A) The origin of the name of this province does not date earlier than A. D. 1200. It was an academical joke; an epithet first applied to the quarrelsome humour of those students in the university of Paris who came from the frontier of France and Flanders, and hence to their country. *Valsi Notitia Galliarum*, p. 447. *Lorguerac, Description de la France*, p. 52.

Piccolo-
mini.

exerted in relieving the necessities of men of letters. He has left behind him a number of works in Italian. The most remarkable of which are, 1. Various Dramatic Pieces, which laid the first foundation of his character as a writer. 2. A Treatise on the Sphere. 3. A Theory of the Planets. 4. A Translation of Aristotle's Art of Rhetoric and Poetry, in 4to. 5. A System of Morality, published at Venice, 1575, in 4to; translated into French by Peter de Larivey in 4to; and printed at Paris, 1581. These, with a variety of other works, prove his extensive knowledge in natural philosophy, mathematics, and theology. He was the first who made use of the Italian language in writing upon philosophical subjects. He died at Sienna the 12th of March 1578, aged 70. A particular catalogue of his works may be seen in the Typographical Dictionary. There is one performance ascribed to this author, intitled *Dialogo della bella Creanta delle Donne*, (printed at Milan, 1558, and at Venice, 1574, in 8vo.); which but ill suits the dignity of a prelate. It is filled with maxims which have an evident tendency to hurt the morals of young women. Piccolomini's name, indeed, is not in the title page; and it has all the appearance of being a juvenile production. It is very scarce; and the public would sustain no loss by its being entirely out of print. It was translated into French by F. d'Amboise, and published at Lyons, in 16mo, under the title of *Instruction des jeunes dames*. It was afterwards reprinted in 1583, under that of *Dialogue & Devis des D. moifelles*.

PICCOLOMINI (Francis), of the same family with the foregoing, was born in 1520, and taught philosophy with success, for the space of 22 years, in the most celebrated universities of Italy, and afterwards retired to Sienna, where he died, in 1604, at the age of 84. The city went into mourning on his death. His works are, 1. Some Commentaries upon Aristotle, printed at Mayence, 1608, in 4to. 2. *Universa Philosophia de Moribus*, printed at Venice, 1583, in folio. He laboured to revive the doctrine of Plato, and endeavoured also to imitate the manners of that philosopher. He had for his rival the famous James Zabarella, whom he excelled in facility of expression and neatness of discourse; but to whom he was much inferior in point of argument, because he did not examine matters to the bottom as the other did; but pressed too rapidly from one proposition to another.

PICCOLOMINI of Aragon (Octavius), duke of Amalfi, prince of the empire, a general of the emperor's army, and knight of the order of the Golden Fleece, was born in 1599. He first bore arms among the Spanish troops in Italy. He afterwards served in the army of Ferdinand II. who sent him to the relief of Bohemia, and entrusted him with the command of the imperial troops in 1634. After having signalized himself at the battle of Nortlingue, he made Marshall de Chastillon raise the siege of St Cmer. He had the good fortune to gain a victory over Marquis de Feuquieres in 1639: nor did the loss of the battle of Wolfenbuttel, in 1651, impair his glory. He died on the 10th of August 1656, being five years after, aged 57, without issue; and with the character of an able negociator and an active general. The celebrated Caprara was his nephew.

PICCOLOMINI (James), whose proper name was Am-

muati, took that of Piccolomini in honour of his patron Pius II. He was born in a village near Lucca in 1422. He became bishop of Massa, afterwards of Fiescati; a cardinal in 1461, under the name of *Cardinal de Pavie*; and died in 1479, at the age of 57, of an indigestion of figs. He left 8000 pistoles in the banker hands, which Pope Sixtus IV. claimed; and of which he gave a part to the Hospital of the Holy Ghost. His works, which consist of some Letters, and a History of his own time were printed at Milan, in 1521, in folio. His history, intitled *Commentari's*, commences the 18th of June 1464, and ends the 6th of December 1469. They may very properly be considered as a Sequel of Pope Pius II.'s Commentaries, which end with the year 1463.

PICCOLOMINI, (Æneas Sylvius) See PIUS II.

PICENTIA, (Strabo, Pliny), the capital of the Picentini, whose territory, called *Ager Picentinus*, a small district, lay on the Tufcan Sea, from the *Promontorium Minervæ*, the south boundary of Campania on the coast, to the river Silarus, the north boundary of Lucania, extending within-land as far as the Samnites and Hirpini, though the exact termination cannot be assigned. The Greeks commonly confound the *Picentini* and *Picentes*, but the Romans carefully distinguish them. The former, with no more than two towns that can be named, *Silernum* and *Picentia*; the situation of both doubtful: only Pliny says the latter stood within-land, at some distance from the sea. Now thought to be *Bivenza*, (Holstenius), in the Principato Citra of Naples.

PICENUM, (Cæsar, Pliny, Florus); PICENUS AGER, (Cicero, Salust, Livy, Tacitus); *Ager picentium*, (Varro): a territory of Italy, lying to the east of Umbria, from the Apennine to the Adriatic; on the coast extending from the river Aesis on the north, as far as the *Præutani* to the south. In the upper or northern part of their territory the Umbri excluded them from the Apennine, as far as Camerinum, (Strabo); but in the lower or southern part they extended from the Adriatic to the Apennine. A very fruitful territory, and very populous. *Picentes*, the people, (Cicero); from the singular, *Picens*, (Livy): different from the *Picentini*, on the Tufcan sea, though called so by the Greeks; but Ptolemy calls them *Piceni*, as does also Pliny. Their territory at this day is supposed to form the greatest part of the March of Ancona, (Cluverius).

PICHFORD, in the county of Salop in England; on the south-east side of Shrewsbury, near Condover. It is noted for a spring of pitchy water (from whence some derive its name), on the top of which there always flows a sort of liquid bitumen. Over most of the coal pits hereabouts there lies a stratum of blackish rock; of which, by boiling and grinding, they make pitch and tar, and also distil an oil from it.

PICHINCHA, a mountain in Peru. See PERU, n^o 56.

PICKERING, in the north riding of Yorkshire in England, 13 miles from Scarborough, and 225 from London, is a pretty large town belonging to the duchy of Lancaster, on a hill among the wild mountains of Blakemore; having the forest of Pickering on the north, and Pickering common on the south. It is said to have been built 270 years before Christ by Peridurus, a king of the Britons, who was buried here. It had once a castle, the ruins of which are still to be seen;

Piccolo-
mini
||
Pickering.

Pickery
Pico.

seen; to whose jurisdiction many of the neighbouring villages were subject: and the adjacent territory, commonly called Pickering-Lath, or the liberty or forest of Pickering, was given by Henry III. to his son Edmund earl of Lancaster. A court is kept here for all actions under 40 s. arising within the honour of Pickering.

PICKERY, in Sico law, petty theft, or stealing things of small value.

PICKETS, in fortification, stakes sharp at one end, and sometimes shod with iron, used in laying out the ground, of about three feet long; but, when used for pinning the fascines of a battery, they are from three to five feet long.

PICKETS, in artillery, are about five or six feet long, shod with iron, to pin the park lines, in laying out the boundaries of the park.

PICKETS, in the camp, are also stakes of about six or eight inches long, to fasten the tent cords, in pitching the tents; also, of about four or five feet long, driven into the ground near the tents of the horsemen, to tie their horses to.

PICKET, an out-guard posted before an army, to give notice of an enemy approaching.

PICKET, a kind of punishment so called, where a soldier stands with one foot upon a sharp pointed stake; the time of his standing is limited according to the offence.

PICKLE, a brine or liquor, commonly composed of salt, vinegar, &c. sometimes with the addition of spices, wherein meat, fruit, and other things, are preserved and seasoned.

PICO, one of the Azore Islands, is so called from some lofty mountains on it; or rather from one very high mountain, terminating like Teneriffe in a peak, and reputed by some writers equal to it in height. This island lies about four leagues south-west from St George, twelve from Terceira, and about three leagues south east of Fayal; in W. Long. 28. 21. and N. Lat. 38. 29. The mountain Pico, which gives name to the island, is filled with dismal dark caverns or volcanoes, which frequently vomit out flames, smoke, and ashes, to a great distance. At the foot of this mountain towards the east is a spring of fresh water, generally cold, but sometimes so heated with the subterraneous fire, as to rush forth in torrents with a kind of ebullition like boiling water; equalling that in heat, and sending forth a steam of sulphureous fetid vapours, liquefied stones, minerals, and flakes of earth all on fire, in such quantities, and with such a violence, as to have formed a kind of promontory vulgarly called *Mysterios*, on the declivity of the coast, and at the distance of 1200 paces from the fountain. Such at least is the account of Ortilius; though we do not find this last circumstance of the promontory confirmed by later observations. The circumference of Pico is computed at about 15 leagues: and its most remarkable places are Pico, Lagoas, Santa Cruce or Cruz, San Sebastian, Pesquin, San Rocho, Playa, and Magdalena, the inhabitants of which live wholly on the produce of the island, in great plenty and felicity. The cattle are various, numerous, and excellent in their several kinds: it is the same with the vine; and its juice, prepared into different wines, the best in the Azores. Besides cedar and other timber, they have a kind of wood which they call *teixo*, solid and hard as iron; and vein-

ed, when finely polished, like a rich scarlet tabby; which colour it has in great perfection. The longer it is kept, the more beautiful it grows: hence it is, that the teixo tree is felled only for the king's use or by his order; and is prohibited from being exported as a common article of trade.

Pico Marina, a sea-fish common at Kongo in Africa, derives its name from the resemblance of its snout to the beak of a wood-pecker. It is of a large size, and prodigious strength, has four fins on its back, three under its belly, and one on each side of its head; its tail is large and forked, by which it cuts the waves with surprising force and velocity. It is at war with every fish that swims, and with every thing it meets in its way, without being intimidated by the largest vessels; a surprising instance of which intrepidity, we are told by some missionaries, whose ship was attacked by one of them, near these coasts, in the dead of night. The violence of the shock which it gave to the vessel quickly awakened the captain and the rest of the people; who immediately ran to the ship's side, where they perceived, by moon light, this huge monster fastened by its forehead to the vessel, and making the strongest efforts to disengage itself; upon which some of them tried to pierce him with their pikes, but he got off before they could accomplish their aim. On the next morning, upon visiting that side of the vessel, they found, about a foot below the surface of the water, a piece of its bony snout stuck fast into the wood, and two or three inches of it projecting outwards. They went presently after to visit the inside of the ship, and discovered about five or six inches more of the point of the horn which had penetrated through the plank.

PICQUERING, a flying war, or skirmish, made by soldiers detached from two armies for pillage, or before a main battle begins.

PICQUET, or PICKET. See PICQUET.

PICRAMNIA, in botany: A genus of the pentandria order, belonging to the diccia class of plants; and in the natural method ranking with those that are doubtful. The calyx is tripartite; the corolla has three petals; the stamina from three to five, and shaped, and seem to join together at the base; there are two styli, which are short and bent backwards; the berry is roundish, and contains two oblong seeds, and sometimes one seed only. There is only one species, viz. the antidesma, or murjoe bush. This shrub is frequent in copses and about the skirts of woods in Jamaica, rising about eight or nine feet from the ground. The leaves are of an oval form, pointed and placed in an alternate form along the branches; the flower spikes are long, pendulous, and slender; the florets small and white: the berries are numerous; at first red, then of a jet black colour; the pulp is soft, and of a purple complexion.—The whole plant is bitter, and especially the berry. The negroes make a decoction of them, and use it in weaknesses of the stomach and in venereal cases.

PICRANIA AMARA, or *Bitter Wood*, is a tall and beautiful timber tree, common in the woods of Jamaica. It is a new genus, belonging to the pentandria monogynia of Linnaeus. The name is expressive of its sensible qualities.

Every part of this tree is intensely bitter; and even after the tree has been laid for floors many years, who-

xiii. p. 26
&c.

ever

Pictis
||
Pictet.

ever rubs or scrapes the wood, feels a great degree of bitterness in their mouth or throat. Cabinet-work made of this wood is very useful, as no insect will live near it.

This tree has a great affinity to the *Quassia Amara* of Linnæus; in lieu of which it is used as an antiseptic in putrid fevers. When used, less of it will do than of the *Quassia Amara* of Surinam. See *QUASSIA*.

PICKIS, Ox-tongue; a genus of the polygamia æqualis order, belonging to the syngenesia class of plants. There are four species, of which the only remarkable one is the echinoides, or common ox-tongue, growing spontaneously in corn fields in Britain. It has undivided leaves embracing the stem, with yellow blossoms, which sometimes close soon after noon, at other times remain open till nine at night. It is an agreeable pot-herb while young. The juice is milky, but not too acid.

PICRUM, in botany: A genus of the monogynia order, belonging to the tetandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is monophyllous and quinquefid; the corolla monopetalous, and its tube is short; the filaments are four in number, and hooded at the place of their insertion; the style long and thick; the stigma bilamellated; the capsule is round, bivalved, and contains a number of small seeds.—There are two species, viz. the *spicata* and *ramosa*; both natives of Guaiana. Both species are bitter, and employed in dyspepsy, and to promote the menses: they are also recommended in visceral obstructions.

PICRET (Benedict), born at Geneva, in 1655, of a distinguished family, prosecuted his studies with great success. After having travelled into Holland and England, he taught theology in his own country with an extraordinary reputation. The university of Leyden, after the death of Spantreina, solicited him to come and fill his place; but he thought that his own country had the best right to his services: and for that generosity he received its thanks by the mouth of the members of council. A languishing disorder, occasioned by too much fatigue, hastened his death; which happened on the 9th of June 1724, at the age of 69 years. This minister had much sweetness and affability in his manner. The poor found in him a comforter and a father. He published a great number of works in Latin and French, which are much esteemed in Protestant countries. The principal of these are, 1. A System of Christian Theology in Latin, 3 vols. in 4to; the best edition of which is that of 1721. 2. Christian Morality, printed at Geneva, 1710, 8 vols. in 12mo. 3. The History of the 11th and 12th centuries; intended as a sequel to that of Sœur, printed in 1713, 2 vols. in 4to. The Continuator is held in higher estimation than the first author. 4. Several Controversial Treatises. 5. A great number of tracts on morality and piety; among which we must distinguish "The Art of Living and Dying well;" published at Geneva, 1705, in 12mo. 6. Some Letters. 7. Some Sermons, from 1697 to 1721; 4 vols. in 8vo. With a vast number of other books, the names of which it would be tedious to mention; but which, as Mr Senneber says, "all show evident marks of piety and good sense."

PICRET (John-Louis), a counsellor of Geneva, born in 1739, was of the same family. He was member of the Council of Two Hundred; Counsellor of State and Syndic; and died in 1781. He applied himself to the study of astronomy, and made several voyages into France and England for his improvement. Few men were ever blessed with a clearer or more enlightened understanding. He has left in manuscript the "Journal of a Voyage which he made to Russia and Siberia in 1768 and 1769, in order to observe the transit of Venus over the sun's disk." A work very interesting, from the lively descriptions which it gives both of men and of nature.

PICTLAND. See **PENTLAND.**

PICTS, the name of one of those nations who anciently possessed the north of Britain. It is generally believed that they were so called from their custom of painting their bodies; an opinion which Camden supports with great erudition. (See Gough's edition, Vol. I. p. xci. of the preface). It is certainly liable, however, to considerable objections; for as this custom prevailed among the other ancient inhabitants of Britain, who used the *glæsum* of Pliny and the *virrum* of Mela for the like purpose, it may be asked, Why the name of *Picti* was confined by the Romans to only one tribe, when it was equally applicable to many others? Why should they design them only by an epithet without ever annexing their proper name? Or why should they impose a new name on this people only, when they give their proper name to every other tribe which they have occasion to speak of? As these questions cannot be answered in any satisfactory manner, it is plain we must look for some other derivation of the name.

The Highlanders of Scotland, who speak the ancient language of Caledonia, express the name of this once famous nation by the term *Pictich*; a name familiar to the ears of the most illiterate, who could never have derived it from the Roman authors. The word *Pictich* means *plunderers* or *plunderers*. The appellation was probably imposed upon this people by their neighbours, or assumed by themselves, some time after the reign of Caracalla, when the unguarded state of the Roman province, on which this people bordered, gave them frequent opportunities of making incursions thither, and committing depredations. Accordingly this name seems to have been unknown till the end of the 3d century. Eumenius the panegyrist is the first Roman author who mentions this people under their new name of *Pictich*, or, with a Latin termination, *Picti*. When we say that this name may have been probably assumed for the reason just now mentioned, we must observe, that, in those days of violence, the character of a robber was attended with no disgrace. If he had the address to form his schemes well, and to execute them successfully, he was rather praised than blamed for his conduct; providing he made no encroachments on the property of his own tribe or any of its allies. We mean this as no peculiar stigma upon the Picts; for other nations of antiquity, in the like rude state, thought and acted as they did. See *Thydidis*, lib. 3. p. 3. and *Virg. Æn.* 7. 745 et 749.

Concerning the origin of the Picts, authors are much divided. Boethius derives them from the Aga-
thyrsi,

Pictet
||
Picts.

r
Name.

2
Origin.

Picts.

thyrsi, Pomponius Lætus from the Germans, Bede from the Scythians, Camden (A) and Father Innes from the ancient Britons, Stillingfleet from a people inhabiting the Cimbria Cherisofesus, and Keating and O'Flaherty, on the authority of the Pfalter Cassel, derive them from the Thracians. But the most probable opinion is, that they were the descendants of the old Caledonians. Several reasons are urged in support of this opinion by Dr Macpherfon; and the words of Eumenes, "Caledonum, antiquum Pictorum, silvas," &c. plainly imply that the Picts and Caledonians were one and the same people.

As there has been much dispute about the origin of the Picts, so there has been much dispute about their language. There are many reasons which make it plain that their tongue was the Gaelic or Celtic; and these reasons are a further confirmation of their having been of Caledonian extract. Through the east and north east coasts of Scotland (which were possessed by the Picts) we meet with an innumerable list of names of places, rivers, mountains, &c. which are manifestly Gaelic.

3 Language. From a very old register of the priory of St Andrew's (Dalrymple's Collections, p. 122.) it appears, that in the days of Hungus, the last Pictish king of that name, St Andrew's was called *Mukrofs*; and that the town now called *Queensferry* had the name of *Ardekinneachan*. Both these words are plain Gaelic. The first signifies "the heath or promontory of bears;" and the latter, "the height or peninsula of Kenneth." In the list of Pictish kings published by Father Innes, most of the names are obviously Gaelic, and in many instances the same with the names in the list of Scottish or Caledonian kings published by the same author. Had Innes understood any thing of this language, he would not have supposed with Camden that the Picts spoke the British tongue. It was unlucky that the two words on which they built their conjecture (*Strath* and *Aber*) are as common in the Gaelic as they could have been in the British, and at this day make a part of the names of places in countries to which the Pictish empire never extended. The names of *Strathfillan* and *Lochsber* may serve as instances.

The venerable Bede, as much a stranger to the Celtic as either of the antiquaries just now mentioned, is equally unhappy in the specimen which he gives of the Pictish language in the word *penuakel*, "the head of the wall." Allowing the commutation of the initial *p* into *c*, as in some other cases, this word has still the same meaning in Gaelic which Bede gives it in the Pictish. It is true, there might have been then, as well as now, a considerable difference between various dialects of the Celtic; and thus, perhaps, that pious author was led to discover five languages in Britain agreeably to the five books of *Moses*: A conceit from which the good man derived a great deal of harmless satisfaction.

4 Territory. The Picts of the earliest ages, as appears from the joint testimony of all writers who have examined the

subject, possessed only the east and north-east coast of Scotland. On one side, the ancient Drumalbin, or that ridge of mountains reaching from Lechlorn and near Dumbarton to the frith of Taine, which separates the county of Sutherland from a part of Ross, was the boundary of the Pictish dominions. Accordingly we find in the life of Columba, that, in travelling to the palace of Brudius, king of the Picts, he travelled over Drumalbin, the *Dorsum Britannie* of Adamnan. On the other side, the territory of the Picts was bounded by the Roman province. After Britain was relinquished by the emperor Honorius, they and the Saxons by turns were masters of those countries which lie between the Frith of Edinburgh and the river Tweed. We learn from Bede, that the Saxons were masters of Galloway when he finished his ecclesiastical History. The Picts, however made a conquest of that country soon after; so that before the extinction of their monarchy, all the territories bounded on the one side by the Forth and Clyde, and on the other by the Tweed and Solway, fell into their hands.

5 History. The history of the Picts, as well as of all the other ancient inhabitants of Britain, is extremely dark. The Irish historians give us a long list of Pictish kings, who reigned over Pictavia for the space of eleven or thirteen centuries before the Christian era. After them Innes, in his Critical Essay, gives us a list of above fifty, of whom no less than five held the sceptre, each for a whole century. It is probable that these writers had confounded the history of the Picts with that of their ancestors the old Caledonians. In any other view, their accounts of them are highly fabulous; and have been long ago confuted by Dr Macpherfon of Slate, an antiquary of much learning and research. The Picts, as has been already observed, were probably not known by that name before the 2d or 3d century. Adamnan, abbot of Iona, is the first author that expressly mentions any Pictish king; and the oldest after him is Bede. We are informed by these two writers, that St Columba converted Brudius king of the Picts to the Christian faith. Columba came into Britain in the year of the vulgar era 565. Before that period we have no general record to ascertain so much as the name of any Pictish king. The history of *Drusi* or *Dress*, who is said to have reigned over the Picts in the beginning of the fifth century, when St Ninian first preached the gospel to that nation, has all the appearance of fiction (B); His having reigned a hundred years, and his putting an end to a hundred wars, are stories which exceed all the bounds of probability.

Brudius, the contemporary of Columba, is the first Pictish king mentioned by any writer of authority.

What figure his ancestors made, or who were his successors on the throne of Pictavia, cannot be ascertained. Bede informs us, that during the reign of one of them, the Picts killed Egfred king of Northumberland in battle, and destroyed the greatest part of

(B) According to Camden, this conversion happened about the year 630, in the southern Pictish provinces; while the northern, which were separated by fruitful mountains, were converted by Columba.

Picts.

his army. The same author mentions another of their kings called *Naitan*, for whom he had a particular regard. It was to this *Naitan* that Ceolfrid, abbot of Wiremouth, wrote his famous letter concerning Easter and the Tonfure (c); a letter in which Bede himself is supposed to have had a principal hand. Roger Hoveden and Simon of Durham mention two other Pictish kings *Onmyll* and *Kinoth*, the first of whom died in 761, and the latter flourished about the 774, and gave an asylum to Alfred of Northumberland, who was much about that time expelled his kingdom. The accounts given by the Scots historians, of several other Pictish kings cannot be depended on; nor are the stories told by the British historians, Geoffry of Monmouth and the author of the *Eulogium Britannie*, worthy of much greater credit.

In the ninth century the Pictish nation was totally subdued by the Scots in the reign of Kenneth Macalpin. Since that time their name has been lost in that of the conquerors, with whom they were incorporated after this conquest; however, they seem to have been treated by the Scottish kings with great lenity, so that for some ages after they commanded a great deal of respect. The prior of Hogulstead, an old English historian, relates, that they made a considerable figure in the army of David the Saint, in his disputes with Stephen king of England. In a battle fought in the year 1136, by the English on one side, and the Scots and Picts on the other, the latter insisted on their hereditary right of leading the van of the Scots army, and were indulged in that request by the king.

The principal feat of the Pictish kings was at Abernethy. Brudius, however, as appears from the accounts given by Adamnan, in his life of Columba, had a palace at Inverness, which was probably near the extremity of this territory in that quarter; for there is no good reason for believing, with Camden, that this king had any property in the Western Isles, or that he had made a gift of Iona to St Columba when he visited him in that place.

6
Manners.

With respect to the manners and customs of the Picts, there is no reason to suppose they were any other than those of the Old Caledonians and Scots, of which many particulars are related in the Greek and Roman writers who have occasion to speak of those nations.

Upon the decline of the Roman empire, cohorts of barbarians were raised, and Picts were invited into the service, by Honorius, when peace was every where restored, and were named *Honoriaci*. Those under Constantine opened the passes of the Pyrenean mountains, and let the barbarous nations into Spain. From this period we date the civilization of their manners, which happened after they had by themselves, and then with the Scots, ravaged this Roman province.

Picts Wall, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf strengthened with palisadoes, till the emperor Severus, coming into Britain in person, built it with solid stone. This wall, part of which still remains, begun at the entrance of the Solway Frith in Cumberland, and running north-east extended to the German Ocean. See ADRIAN and SEVERUS.

PICTURE, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like. See PAINTING.

PICTURESQUE BEAUTY, says a late writer on that subject, refers to "such beautiful objects as are suited to the pencil." This epithet is chiefly applied to the works of nature, though it will often apply to works of art also. Those objects are most properly denominated picturesque which are disposed by the hand of nature with a mixture of *varied rudeness*, *simplicity*, and *grandeur*. A plain neat garden, with little variation in its plan, and no striking grandeur in its position, displays too much of art, design, and uniformity, to be called picturesque. "The ideas of *neat* and *smooth* (says Mr Gilpin), instead of being picturesque, in fact disqualify the object in which they reside from any pretensions to picturesque beauty. Nay, farther, we do not scruple to assert, that roughness forms the most essential point of difference between the beautiful and the picturesque; as it seems to be that particular quality which makes objects chiefly pleasing in painting. I use the general term *roughness*; but properly speaking roughness relates only to the surfaces of bodies: when we speak of their delineation, we use the word *ruggedness*. Both ideas, however, equally enter into the picturesque, and both are observable in the smaller as well as in the larger parts of nature; in the outline and bark of a tree, as in the rude summit and craggy sides of a mountain.

"Let us then examine our theory by an appeal to experience, and try how far these qualities enter into the idea of picturesque beauty, and how far they mark that difference among objects which is the ground of our inquiry.

"A piece of Palladian architecture may be elegant in the last degree; the proportion of its parts, the propriety of its ornaments and the symmetry of the whole, may be highly pleasing; but if we introduce it in a picture, it immediately becomes a formal object, and ceases to please. Should we wish to give it picturesque beauty, we must use the mallet instead of the chisel; we must beat down one half of it, deface the other, and throw the mutilated members around in heaps; in short, from a smooth building we must turn it into a rough ruin. No painter who had the choice of the two objects would hesitate a moment.

"Again,

(c) We are told by some authors that Columba taught the Picts to celebrate Easter always on a Sunday between the 14th and 20th of March, and to observe a different method of tonfure from the Romans, leaving an imperfect appearance of a crown. This occasioned much dispute till Naitan brought his subjects at length to the Roman rule. In that age many of the Picts went on a pilgrimage to Rome, according to the custom of the times; and amongst the rest we find two persons mentioned in the antiquities of St Peter's church: *Astirius* count of the Picts, and *Syru* with his countrymen, performed their vow,

Picts Wall
||
Picturesque
beauty.

Pictureque beauty. "Again why does an elegant piece of garden-ground make no figure on canvas? the shape is pleasing, the combination of the objects harmonious, and the winding of the walk in the very line of beauty. All this is true; but the smoothness of the whole, though right and as it should be in nature, offends in picture. Turn the lawn into a piece of broken ground plant rugged oaks instead of flowering shrubs, break the edges of the walk, give it the rudeness of a road, mark it with wheel-tracks, and scatter around a few stones and brushwood; in a word, instead of making the whole smooth, make it rough, and you make it also pictureque. All the other ingredients of beauty it already possessed." On the whole, pictureque composition consists in uniting in one whole, a variety of parts, and these parts can only be obtained from rough objects.

It is possible therefore to find pictureque objects among works of art, and it is possible to make objects so; but the grand scene of pictureque beauty is nature in all its original variety, and in all its irregular grandeur. "We seek it (says our author) among all the ingredients of landscape, trees, rocks, broken grounds, woods, rivers, lakes, plains, valleys, mountains, and distances. These objects in themselves produce infinite variety; no two rocks or trees are exactly the same; they are varied a second time by combination; and almost as much a third time by different lights and shades and other aerial effects. Sometimes we find among them the exhibition of a whole, but oftener we find only beautiful parts."

Sublimity or grandeur alone cannot make an object pictureque: for, as our author remarks, "however grand the mountain or the rock may be, it has no claim to this epithet, unless its form, its colour, or its accompaniments, have some degree of beauty. Nothing can be more sublime than the ocean; but wholly unaccompanied, it has little of the pictureque. When we talk therefore of a sublime object, we always understand that it is also beautiful; and we call it sublime or beautiful only as the ideas of sublimity or simple beauty prevail. But it is not only the form and the composition of the objects of landscape which the pictureque eye examines, it connects them with the atmosphere, and seeks for all those various effects which are produced from that vast and wonderful storehouse of nature. Nor is there in travelling a greater pleasure than when a scene of grandeur bursts unexpectedly upon the eye, accompanied with some accidental circumstance of the atmosphere which harmonizes with it, and gives it double value."

There are few places so barren as to afford no pictureque scene.

————— Believe the muse,
She does not know that inauspicious spot
Where beauty is thus niggard of her store.
Believe the muse, through this terrestrial waste
The seeds of grace are sown, profusely sown,
Even where we least may hope. ———

Mr Gilpin mentions the great military road between Newcastle and Carlisle as the most barren tract of country in England; and yet there, he says, there is "always something to amuse the eye. The interchangeable patches of heath and green-sward make an

agreeable variety. Often too on these vast tracts of intersecting grounds we see beautiful lights, softening off along the sides of hills; and often we see them adorned with cattle, flocks of sheep, heath-cocks, grouse, plover, and flights of other wild fowl. A group of cattle standing in the shade on the edge of a dark hill, and relieved by a lighter distance beyond them, will often make a complete picture without any other accompaniment. In many other situations also we find them wonderfully pleasing, and capable of making pictures amidst all the deficiencies of landscape. Even a winding road itself is an object of beauty; while the richness of the heath on each side, with the little hillocks and crumbling earth, give many an excellent lesson for a fore ground. When we have no opportunity of examining the grand scenery of nature, we have every where at least the means of observing with what multiplicity of parts, and yet with what general simplicity, she covers every surface.

"But if we let the imagination loose, even scenes like these administer great amusement. The imagination can plant hills; can form rivers and lakes in valleys: can build castles and abbeys; and if it find no other amusement, can dilate itself in vast ideas of space.

Mr Gilpin, after describing such objects as may be called pictureque, proceeds to consider their sources of amusement. We cannot follow our ingenious author through the whole of this consideration, and shall therefore finish our article with a short quotation from the beginning of it. "We might begin (says he) in moral style, and consider the objects of nature in a higher light than merely an amusement. We might observe, that a search after beauty should naturally lead the mind to the great origin of all beauty; to the

—————first good, first perfect, and first fair.

But though in theory this seems a natural climax, we insist the less upon it, as in fact we have scarce ground to hope that every admirer of pictureque beauty is an admirer also of the beauty of virtue; and that every lover of nature reflects, that,

Nature is but a name for an *essèd*,
Whose *cause* is God. ———

If, however, the admirer of nature can turn his amusements to a higher purpose; if its great scenes can inspire him with religious awe, or its tranquil scenes with that complacency of mind which is so nearly allied to benevolence, it is certainly the better. *Apponatur lucro.* It is so much into the bargain; for we dare not promise him more from pictureque travel than a rational and agreeable amusement. Yet even this may be of some use in an age teeming with licentious pleasure; and may in this light at least be considered as having a moral tendency."

PICUIPINIMA, in ornithology, is the name of a species of pigeon in Brasil. It is so very small as scarce to exceed the lark in size. Its head, neck, and wings, are of a pale lead colour, with a black semilunar mark at the extremity of each wing; but its long wing-feathers, which are seen when the wings are expanded in flying, are of a reddish brown on one side, and blackish on the other, with black ends or tips; the tail is long,

Picumnus, long, and is variegated with black, white and brown; the belly is covered with white feathers, every one of which has a brown mark of the shape of a half moon at the end.

PICUMNUS and PILUMNUS, were two deities at Rome, who presided over the auspices required before the celebration of nuptials. Pilumnus was supposed to patronize children, as his name seems in some manner to indicate *quod pellat mala infantis*. The manuring of land was first invented by Picumnus, from which reason he is called *Sterquilinus*. Pilumnus is also invoked as the god of bakers and millers, as he is said to have first invented the art of grinding corn.

PICUS, the WOODPECKER, in ornithology, a genus belonging to the order of picæ. The beak is straight and consists of many sides, and like a wedge at the point; the nostrils are covered with bristly feathers; the tongue is round like a worm, very long, and sharp at the point, which is beset with bristles bent backwards.

The grand characteristic, says Latham, of these birds is the tongue (which in no bird is similar, the wryneck excepted, whose other characters, however, differ too widely to give it place in this class), the muscles necessary to the motions of which are singular and worthy of notice; affording the animal means of darting it forwards the whole length, or drawing it within the mouth at will. See *Ray on the Creation*, p. 143. *Derham's Physic. Theol.* p. 342. Note c. *Will. Orn.* p. 136. t. 21.

The same intelligent ornithologist enumerates no less than 50 different species of woodpeckers, besides varieties of some of them which amount to nine more. Each of these species our readers cannot expect us to describe; we shall therefore content ourselves with such as appear to be most remarkable.

1. The *picus martius*, or greatest black woodpecker, is about the size of a jackdaw, being about 17 inches long; the bill is nearly two inches and a half in length, of a dark ash-colour, and whitish on the sides; the irides are pale yellow, and the eye lids are naked, according to Scopoli; the whole bird is black, except the crown of the head, which is vermillion; the first quill-feather is the shortest, and the two middle tail-feathers, which are longer than the others, make it appear a little rounded, the legs are of a lead colour, covered with feathers on the forepart for half their length.

The female differs from the male in having the hind head only red, and not the whole crown of the head; and the general colour of the plumage has a strong cast of brown in it. It has likewise been observed, that the red on the hind head has been wholly wanting; and indeed both male and female are apt much to vary in different subjects; some having a much greater proportion of red on the head than others. This species is found on the continent of Europe, but not in plenty except in Germany. It is not an inhabitant of Italy, and is very rarely seen in France. Frisch mentions it as a bird common to his parts; and it is found also in Sweden, Switzerland, and Denmark, but not in winter.

It is said to build in old ash and poplar trees, making large and deep nests; and Frisch observes, that they often excavate a tree, that it is soon after blown

down with the wind; and that under the hole of this bird may often be found a bushel of dust and bits of wood. The female lays two or three white eggs, the colour of which, as Willoughby observes, is peculiar to the whole of the woodpecker genus, or at least all those which have come under his inspection."

2. The *picus principalis*, or white billed woodpecker, is somewhat bigger than the last, being equal in size to a crow. It is 16 inches long, and weighs about 20 ounces. The bill is white as ivory, three inches long and channelled; the irides are yellow, and on the hind head is an erect pointed crest, of a fine red colour some of the feathers of which are two inches long; the head itself, and the body in general are black; but the lower part of the back, rump, and upper tail-coverts, are white; from the eye there arises a stripe of white, which passes on each side of the neck down to the back; three or four of the prime quills are black, but the rest are white; the tail is cuneiform, and of the same colour as the body; the legs and claws are also black.

This species inhabits Carolina, Virginia, New Spain, and Brasil, and is called by the Spaniards *carpenter*, and not without reason, as this as well as most of the other species make a great noise with the bill against the trees in the woods, where they may be heard at a great distance, as if carpenters were at work, making, according to Catsby, in an hour or two a bushel of chips. He adds likewise, that the Canadian Indians make use of the bills of these birds for cornets, setting them round in a wreath with the points outwards; and that the northern Indians purchase them of the southern at the rate of two and three buck skins per bill. Kalm says they are found in New Jersey, though very seldom, and only at certain seasons."

3. The *picus erythrocephalus*, or red headed woodpecker, is about eight inches three quarters long, and weighs two ounces. The bill is an inch and a quarter in length, of a lead colour, with a black tip; the irides are dusky, the head and the neck are of a most beautiful crimson; the back and wings are black; the rump, breast, and belly, are white; the ten first quills are black, the eleventh black and white, and the others are white with black shafts; the tail is black and cuneiform; the legs and claws are of lead colour. The cock and hen are very nearly alike.

This species inhabits Virginia, Carolina, Canada, and most of the parts of North America; but at the approach of winter it migrates more or less to the southward, according to the severity of the season; and upon this circumstance the people of North America foretel the rigour or clemency of the ensuing winter. Kalm observes that it is a very common bird, and is very destructive to the maize fields and orchards, pecking through the ears of maize, and destroying great quantities of apples. In some years they are more numerous than in others, when they attack the orchards where the sweet apples grow, which they eat so far that nothing remains but the mere pills. Some years since there was a premium of twopence per head paid from the public fund, in order to extirpate this pernicious bird; but this has been neglected much of late. They are said likewise to be very fond of acorns. In Virginia and Carolina they stay the whole year, but

Picus.

Picus.

are not seen in such numbers in winter as in summer. During the winter they are very tame, and are frequently known to come into the houses in the same manner as the red breast is wont to do in England. It is observed that this species is found chiefly in old trees; and the noise they make with their bills may be heard above a mile distant. It builds the earliest of all the woodpeckers, and generally pretty high from the ground. It is accounted by many people very good eating. Buffon is of opinion, that it is necessity alone that causes these birds to feed on vegetables of any kind, as it is contrary to the nature of the genus."

4. The picus pubescens, or little woodpecker, according to Catesby, weighs only about an ounce and an half. Brisson says, it is larger than the smallest of the European species being about five inches and a half long. The bill is about eight lines long, and of a horn colour; the top of the head is black, and on each side above the eye is a white line; the hind head is red; the hind part of the neck, the back, and rump, are black, which is divided into two parts by a line of white passing down the middle to the rump; the scapulars, upper wing and tail coverts are black; the greater wing coverts and quills are spotted with white; the under parts of the body are pale grey; the tail is black; the four middle feathers are plain, the rest are barred with white and black; and the legs and claws are black.

The female has no red on the hind head. Linnaeus tells us, that the outer tail feather is white, marked with four black spots. This species inhabits Virginia and Carolina. According to Kalm, it abounds in New Jersey, where it is esteemed of all others the most dangerous to orchards, and is the most daring. As soon as it has pecked one hole in a tree, it makes another close to the first, in an horizontal direction, proceeding till it has made a circle of holes quite round the tree; and the apple-trees in the orchards, have often several of these rings of holes round the stem, inasmuch that the tree frequently dries up and decays.

5. The yellow woodpecker is about nine inches long. The bill is of a yellowish white, and more than an inch long; the hind head is crested; the head itself, the neck, and whole body, are covered with dirty white feathers; from the lower jaw to the ears on each side, there is a red stripe; the wing coverts are brown and edged with yellowish, and some of the greater ones are mixed with rufous on the inner web; the quills are brown or rufous; the tail is black; the legs and claws are grey.

"This species is common at Cayenne, and is called there *charpentier jaune*. It makes its nest in old trees which are rotten within; making with its bill a hole from without, at first horizontal, but declining down-

Picus.

wards as soon as it has pierced through the sound part, till it is at last a foot and a half below the first opening. The female lays three white and nearly round eggs, and the young are hatched about the beginning of April. The male bears his share in the work with the female, and in her absence keeps sentinel at the entrance of the hole. The note of this bird is a kind of whistle six times repeated, of which the two or three last are in a graver accent than the others. The female wants the red band on the side of the head which is seen in the male.

"Specimens vary; some are of that dirty white, as Brisson describes it, others of a light yellow; which last is the case in a specimen in the Leverian museum: This is 13 inches in length.

"In the place referred to above, we find a bird imperfectly described by Mr Fermin: he merely says, that it is a large species; that it has a fine red crest on the head; the neck, breast, and belly, of a citron colour; and the wings blueish above. He only adds, that it may be distinguished from others by the strokes of the bill, which it gives to the trees, and may be heard at a great distance."

6. The picus auratus, or gold-winged woodpecker, is about 11 inches long, and weighs about 5 ounces. The bill is an inch and a half long, and is somewhat bent, and is not square but roundish, ridged only on the top, the point being sharp; the upper parts of the head and neck are ash-coloured; the hind head is red; the sides of the head, throat, and fore-part of the neck, are pale yellow; on each side of the head is a stripe of black, from the base of the lower jaw to the neck; the back, scapulars, and wing coverts, are of a grey brown colour, transversely striated with black lines; the rump is whitish; the breast, belly, and sides, are whitish yellow, and each feather is marked with a round black spot at the tip; on the middle of the breast there is a large crescent of black; the thighs, upper and under tail coverts, are black and white mixed; the quills are brown, with yellow shafts spotted with brown on the outer edge; the tail is blackish, being outwardly edged with grey; the outer feather is dotted with whitish on the margins; the shafts of all but the two middle feathers are yellow half way from the base; and the legs and claws are brown.

The female differs in having the crown and neck behind, grey brown; the hind head of a less vivid red; and the greater quills not spotted on the edges. She also wants the black list on the throat, but otherwise like the male.

This species inhabits Carolina, Virginia, and Maryland, and is plenty in the middle states, where it is called by some *hittcock* or *pink*, and by others *high hole* (A). Both the first names have some relation to its

(A) "I have lately seen (says Latham) in the Leverian museum a bird which appears to be a mere variety though brought from a far different country. This was much like the picus auratus in colour, but rather less in size. The bill made exactly like that bird, and brown; on each side of the jaw is a stripe of crimson like a whisker; the under part of the wings of a pale red colour, not unlike what is called *red lead*; and the shafts of the quills and tail, which in the other bird are yellow, in this are red; the plumage on the upper parts of the body is brown, beneath vinaceous, marked with round black spots; tail black, pointed, and each feather bifurcated at the tip, exactly like the American one. This was brought from the Cape of Good Hope. I have seen two specimens of this bird."

Picus.

its note; and perhaps the latter, from the situation of the nest. It is almost continually on the ground, and is not observed to climb on the trees, like others of the genus. It lives chiefly on insects (b), and is commonly very fat, so as to be thought very palatable for the table. It stays all the year; and as it cannot at all times get insects, it must perhaps eat some kind of grafs or plants in the fields. Its form and some of its qualities make it resemble the cuckow (c). Though it climbs not on trees, it flies to their tops and sits occasionally on the branches.

Forster, in the Philosophical Transactions, observes, that it is a bird of passage in the northern parts of America, visiting the neighbourhood of Albany Fort in April, and leaving it in September: that it lays from four to six eggs, in hollow trees, and feeds on worms and other insects. Called by the natives *ou-thee-quan-noro*.

The following species are pretty well known in Britain.

7. The viridis, or green woodpecker, weighs six ounces and a half; its length is 13 inches, the breadth 20 and a half; the bill is dusky, triangular, and near two inches long; the crown of the head is crimson, spotted with black; the eyes are surrounded with black, and the males have a rich crimson mark beneath the blackness; the back, neck, and lesser coverts of the wings, are green; the rump of a pale yellow; the whole of the under part of the body is of a very pale green, and the thighs and vent are marked with dusky lines; the legs and feet are of a cinereous green; the tail consists of ten stiff feathers, whose ends are generally broken, as the bird rests on them in climbing; their tips are black; the rest of each is alternately barred with dusky and deep green. These birds feed entirely on insects; and their principal action is that of climbing up and down the bodies or boughs of trees: for the first purpose they are provided with a long slender tongue, armed with a sharp bony end barbed on each side, which by the means of a curious apparatus of muscles, they can exert at pleasure, darting it to a great length into the cliffs of the bark, transfixing and drawing out the insects that lurk there. They make their nests in the hollows of trees: in order therefore to force their way to those cavities, their bills are formed strong, very hard, and wedge-like at the end; Dr Derham observes, that a neat ridge runs along the top, as if an artist had designed it for strength and beauty. Yet it has not power to penetrate a sound tree; their perforation of any tree is a warning to the owner to throw it down. Their legs are short, but

strong; their thighs very muscular; their toes disposed two backward, two forward; the feathers of the tail are very stiff, sharp-pointed, and bending downwards. The three first circumstances do admirably concur to enable them to run up and down the sides of the trees with great security; and the strength of the tail supports them firmly when they continue long in one place, either where they find plenty of food, or while they are forming an access to the interior part of the timber. This form of the tail makes their flight very awkward, as it inclines their body down, and forces them to fly with short and frequent jerks when they would ascend, or even keep in a line. This species feeds oftener on the ground than any other of the genus: all of them make their nests in the hollows of trees; and lay five or six eggs, of a beautiful semitransparent white.

Willoughby says that the female lays five or six eggs; which Pennant (d) also observes; adding that they are of a beautiful semitransparent white.

“These birds sometimes build in a hollow asp or other tree, 15 or 20 feet from the ground. The male and female take it by turns to bore through the living part of the wood, till they come to the rotten part, wherein, after being hollowed out to a proper depth, they lay their eggs (e), which are generally five and sometimes six (f) in number, greenish with small black spots. The young ones climb up and down the trees before they can fly. It is worthy of remark to observe with what nicety the holes of the woodpecker are made, as perfectly round as if made by the assistance of a pair of compasses. Nuthatches, starlings, and bats, frequently build in these holes when deserted.

“Both Frisch and Klein mistake in saying that the females have not the red crown, for even the young ones in the nest have the appearance of it; and I have had them brought to me when they could scarcely fly, when the red was mixed with brown; but they do not become of a full red till after the first moult. They are said to be fond of bees in winter, making great havock among them. Salerne observes, that they are found in the markets in Italy, at Bologna; but this is not extraordinary, for the Italians eat all small birds almost without exception.

“In Sir A. Lever’s museum there is a variety of this bird, of a straw-colour throughout, except the crown, which is faintly marked with red.”

8. The major, or great spotted woodpecker, weighs two ounces three quarters; the length is nine inches; the breadth is 16. The bill is one and a quarter long, of a black horn colour. The irides are red. The forehead

(b) “In defect of insects I have been informed (says Mr Latham), that it feeds on the berries of the red cedar, and grows fat on them. This food has been both digorged by the mouth, after being shot, as well as found in the stomach on dissection.”

(c) “Linnaeus, in his tenth edition of the *Systema Naturae*, had ranked this with the cuckows; and Buffon, from its similarity to this genus, has placed it at the end of the wood peckers of its class.”

(d) *Br. Zool.* p. 242. where some pertinent observations on these birds may be found. Let the reader also consult *Ray on the Creation*, p. 143. and *Derham’s Physico-theol.* p. 193, 339, 342.

(e) “This is sometimes so deep that they must feed their young quite in the dark; for I have been told by one, that he was obliged to thrust his whole arm to the shoulder down the hollow of a tree before he could reach the eggs.”

(f) “I have seen six young ones together in one nest.” *Will. Orn.* p. 136.

Picus.

Picus.

head is of a pale buff colour; the crown of the head a glossy black; the hind-part marked with a rich deep crimson spot. The cheeks are white; bounded beneath by a black line that passes from the corner of the mouth and surrounds the hind-part of the head. The neck is encircled with a black colour. The throat and breast are of a yellowish white; the vent feathers of a fine light crimson. The back, rump, and coverts of the tail, and lesser coverts of the wings, are black; the scapular feathers and coverts adjoining to them are white. The quill feathers are black, elegantly marked on each web with round white spots. The four middle feathers of the tail are black, the next tipped with dirty yellow; the bottoms of the two outermost black; the upper parts of a dirty white. The exterior feathers marked on each web with two black spots; the next with two on the inner web, and only one on the other. The legs are of a lead colour. The female wants that beautiful crimson spot on the head; in other respects the colours of both agree. This species is much more uncommon than the preceding; and keeps altogether in the woods. This bird is pretty common in England, France, Germany, and other parts of Europe, frequenting the woods like the rest of its genus, and is likewise met with in America. It is a very cunning bird; for when a person has seen one on a tree, he is almost sure to lose sight of it, if the tree is large, and the observer not very attentive; for the moment it spies any one it will creep behind a branch, and there lie secure till the danger is over. The extreme facility with which birds of the woodpecker kind descend as well as ascend the trees is worthy admiration, seeming to do both with equal ease to itself. We do not find any one who has noticed the colour of the eggs; but Buffon mentions having found a nest with six young ones in an old decayed asp tree, 30 feet from the ground.

9. The medius or middle-sized woodpecker, agrees with the preceding in colours and size, excepting that the crown of the head in this is of a rich crimson; the crown of the head in the male of the former black; and the crimson is in form of a bar on the hind part. Birds thus marked have been shot in Lancashire and other parts of England; but Mr Pennant is doubtful whether they are varieties or distinct species. "Buffon (says Latham), quotes many authors who have described this bird, but I am not clear in its being a distinct species. It is certainly much more scarce in England than any other. Buffon is reconciled to its being a variety only; but if so, this variety is regular, at least, in all the specimens which I have seen."

10. The minor, or least spotted woodpecker, scarce weighs an ounce: the length is six inches; the breadth eleven. The forehead is of a dirty white; the crown of the head (in the male) of a beautiful crimson: the cheeks and sides of the neck are white, bounded by a bed of black beneath the former. The hind part of the head and neck, and the coverts of the wings, are black: the back is barred with black and white: the scapulars and quill-feathers spotted with black and white: the four middle feathers of the tail are black; the others varied with black and white: the breast and belly are of a dirty white: the crown of the head (in the female) is white; the feet are of a lead colour. It has all the characters and actions of the greater kind,

but is not so often met with. Salerne tells us that this bird is not found in France; but Buffon affirms that it inhabits most of the provinces there. It approaches near habitations in winter, and may be seen in orchards adjoining to houses, which no doubt it does for the sake of food, finding about the trunks of the trees both caterpillars and larvæ of insects of all kinds. It builds in an hole of a tree, and often disputes the right of possession with the little colemouse, which last, as it is much weaker of the two, must yield the victory. Willoughby says it is called in England by the name of *hickwall*. Linnæus, in his synonyms of this bird, quotes Hæffelquist for the fame; but whoever will diligently read what this author says of the matter, will be convinced that the reference should be to the greater rather than the least of this genus. It is said by him to inhabit the higher parts of Asia.

Mr Sonnerat mentions a bird found by him at Antigue, in the island of Panay, with the top of the head, and hind part of the neck, of a greyish black: on each side of the neck, two-thirds downwards, is a stripe of white, which begins just above the eye; and under this another of black from the eye to the shoulder. The upper part of the body is black and white. The under parts pale yellow, spotted with black. The tail is black above, and beneath barred with a dirty white and yellowish colour. The bill and legs blackish. The head had no red on it. Buffon supposes it to have been a female, and a variety only of our least spotted woodpeckers.

Picus (fab. hist.), a king of Latium, son of Saturn. He married Venilia, also called Canens, by whom he had Faunus. He was tenderly loved by the goddess Pomona, and he returned her affection. As he was one day hunting in the woods, he was met by Circe, who became deeply enamoured of him, and who changed him into a woodpecker, called by the name of *picus* among the Latins. His wife Venilia was so disconsolate when she was informed of his death, that she pined away. Some suppose that Picus was the son of Pilumnus, and that he gave out prophecies to his subjects by means of a favourite woodpecker; from which circumstance originated the fable of his being metamorphosed into a bird.

Picus (John), earl of Miranda, a prodigy of parts and learning, was the youngest child of John Francis Picus earl of Miranda and Concordia; and was born in the year 1463. The progress that he made in letters was so extremely rapid, that it was matter of astonishment to see even a boy one of the first poets and orators of his age. He was the scholar of R. Jochanan, a German Jew, who confirmed his natural fondness for the cabalistical writings, inasmuch that he is reported to have declared, that those who dived into them dived in the true head spring; whereas those rivulets that had flowed thence into Greece were no better than corrupt and stagnated waters. After visiting the most famous universities of France and Italy, he went to Rome; where, in 1486, before he was 24 years of age, he published 900 propositions in logic, mathematics, physics, divinity, cabalistic learning, and magic, drawn not only from Greek and Latin, but even from Jewish and Arabian writers; subjoining to his advertisement, that, "if any philosopher or divine would come to Rome to dispute with

Picus.

Picus
Pieces.

him upon any or all of them, he would defray the expences of his journey from the remotest corners of Italy". He enjoyed, however, the honour of this disputations challenge quietly, without danger to his credit: for envy procured some of his propositions to be charged with herefy, and he was forbid to dispute upon them. As a proof of the ignorance of his opposers, we are told that a theologian who had shewn himself very zealous in censuring his book, being asked what was the meaning of the word *cabbala*? answered, that he was a wicked man and a heretic, who had written against Jesus Christ, and that those who followed his opinion were called cabbalists. At the age of 28, he confined himself wholly to the study of the scripture; and undertook to combat the Jews and Mahometans, as well as to confound judicial astrology; but in this intention his credit was also sived, though with the loss of his life, by his dying in 1494, in his 32d year. He was called the *phoenix of his age*, and by Scaliger *Monstrum sine Vitio*. He composed a great number of works, which have often been printed both separately and together. The following epitaph is upon his tomb:

*Hic situs est Pius Mirandola, cetera norunt
Et Tagus et Ganget, forsan et Antipodes.*

PICUS (John Francis), prince of Mirandola, nephew of John Picus mentioned above, was born about the year 1469. He cultivated learning and the sciences after the example of his uncle; but he had a principality and dominions to superintend, which involved him in great troubles, and at last cost him his life. He was twice driven from his principality, and twice restored; and at last, in 1533, was, together with his eldest son Albert, assassinated in his own castle by his nephew Galeoti. He was a great lover of letters; and such of his works as were then composed were inserted in the Strasburgh edition of his uncle's in 1504, and continued in future impressions, besides some others which were never collected.

PIECE, in matters of money, signifies sometimes the same thing with species; and sometimes, by adding the value of the pieces, it is used to express such as have no other particular name. For the piece of eight, or piastre, see *MONET-Table*.

PIECE, is also a kind of money of account, or rather a manner of accounting used among the negroes on the coast of Angola in Africa, See *MONET-Table*.

PIECE, in heraldry, denotes an ordinary or charge. The honourable pieces of the shield are the chief, fess, bend, pale, bar, cross, saltier, chevron, and in general all those which may take up one-third of the field, when alone, and in what manner soever it be. See *HERALDRY*.

PIECE, in the military art, include all sorts of great guns and mortars. Battering pieces are the larger sort of guns used at sieges for making the breaches; such are the 24-pounder and culverine, the one carrying a 24 and the other an 18 pound ball. Field-pieces are 12 pounders, demiculverines, 6-pounders, sakers, minions, and 3 pounders, which march with the army, and encamp always behind the second line, but in day of battle are in the front. A soldier's firelock is likewise called his *piece*.

PIEDMONT, a country of Italy, with the title Piedmont. of a principality, is bounded on the north by Savoy and Italy; on the west by France; on the south by the Mediterranean and the republic of Genoa; and on the east by the duchies of Montferrat and Milan; extending about 150 miles from north to south, but much less from east to west. It is called Piedmont, and in Latin *Piedmontium*, from its situation at the foot of the mountains, or Alps, which separate France from Italy. This country is in some parts mountainous, but is every where very fruitful. The plains produce fine corn; and Montferrat and the Milanese yield great quantities of Turkey wheat, which commonly serves for bread; and with which the people of the middle rank mix rye; the pods are used for fuel, and the stalks being thick serve to mend the roads. The hills produce plenty of wine, which, like the Italian wines, is very luscious when new, especially the white. There is also a tartish red wine called *vino brusco*, said to be very wholesome for fat people, and, on the other hand, the sweet wine is recommended as a stomachic. The neighbourhood of Turin is famous for its fine fruits, and many long walks of chestnut and mulberry trees, which produce both pleasure and profit. Marons; or large chestnuts, are a favourite dainty among the common people. These are put into an oven, and, when thoroughly hot, and cooled in red wine, are dried a second time in the oven, and afterwards eaten cold. Truffles grow here in such abundance, that Piedmont has obtained the name of the *truffle country*. Some are black, others white marbled with red. Their price is rated according to their size. Sometimes they are found of 12 or 14 pounds weight; and many country people earn from 60 to 70 dollars a-year merely by digging for them. The trade in cattle is said to bring into Piedmont no less than three millions of livres per annum. The cultivation of silk is also a profitable article, the Piedmontese silk being, on account of its fineness and strength, esteemed the best in Italy. The Piedmontese gentry breed vast numbers of silk-worms under the care of their tenants, who have the eggs and mulberry leaves delivered to them, and in return they give half the silk to their masters. This principality comprehends eleven small provinces: Piedmont proper, the valleys between France and Italy, the valley of Saluzza, the county of Nice, the Marquisate of Susa, the duchy of Aost, the Canavese, the lordship of Vercelli, the county of Asti, and the Langes. It was formerly a part of Lombardy, but now belongs to the king of Sardinia, and lies at the foot of the Alps, which separate France from Italy. It contains many high mountains, among which there are rich and fruitful valleys, as pleasant and populous as any part of Italy. In the mountains are mines of several kinds; and the forests afford a great deal of curious game, among which the *tumor* is an useful animal. "The mules (says Mr Watkins) are very fine in this country; but the inhabitants have other beasts, or rather monsters, which they find very serviceable, though vicious and obdurate. These are produced by a cow and an ass, or mare and bull, and called *jumarres* or *gimurri* (A). I cannot say that I have ever seen any of them, but I am told they are very common."

The

(A) These equivocal animals, however, if we may so term them, are so generally mentioned by travellers in

Piedmont. The Piedmontese have more sense than the Savoyards, but then they are not so sincere. Some authors represent them as lively, artful, and witty, the inhabitants of the mountain of Aosta excepted, who are farther distinguished by large wens, as even their horses, dogs, and other animals. Mr Baretto, however, in his *Account of Italy*, vol. ii. p. 116. gives the following account of them. "One of the chief qualities (says he), which distinguish the Piedmontese from all other Italians, is their want of cheerfulness. Piedmont never produced a single good poet, as far as the records of the country can go, whereas there is no other province of Italy but what can boast of some poet ancient or modern; and yet the Piedmontese are not deficient in several branches of learning, and some of them have succeeded tolerably well in civil law, physic, and the mathematics. It is likewise observed of this people, that none of them ever attained to any degree of excellence in the polite arts, and it is but lately that they can boast of a painter, Cavaliero Bamente; a statuary, Signor Lodeito; and some architects, Conte Alisieri, Signor Borra, and others, who yet, to say the truth, are far inferior to numberless artists produced by the other provinces of Italy. They have, on the other hand, greatly advanced when considered as soldiers; though their troops have never been very numerous, every body conversant in history knows the brave stand they made for some centuries past against the French, Spaniards, and Germans, whenever they have been invaded by these nations. The skill of the Piedmontese in fortification is likewise very great, and their Bertolas and Pintos have shown as much genius as the Vautubans and Cohorns, in rendering impregnable several places which inferior engineers would only have made secure."

Payne's
Geog.
vol. iii.

The chief trade of this principality consists in hemp and silk. Indeed, so great is their trade in raw silk, that the English alone have purchased to the value of 200,000 lb. in a year. The silk worm thrives so well, that many peasants make above (b) 100 lb. of silk annually; and it is not only abundant, but universally known to be stronger and finer than any in Italy. The land owners divide the profit with their tenants. The Piedmontese workmen, however, are said to want expertness, though they finish their work equally well with those of other nations. The high duty and land-carriage on mules likewise tend to lessen the value of this trade. They have besides corn, rice, wine, fruits, flax, and cattle.

In the valleys of Luccerne, Peyrouse, and St Martin, which have always belonged to Piedmont, live the celebrated Waldenses or Vaudois, a name which signifies *people of the valleys*. These have rendered themselves famous in history for their dissent from the Romish church long before the time of Luther and Calvin, and for the persecutions they have suffered on that account; but since the year 1730 they have not been openly molested for their religion, but, in order to suppress them

by degrees, a popish church has been built in every parish. They are heavily taxed, and labour under great oppressions. The number of people in these valleys since at present exceeds 10,000, of which 1000 are Catholics. The chief river of Piedmont is the Po, which flows out of Mount Viso. The river Sesia, the Doria, Baltea, the ancient Drunia, the Tenaro, and several others, run into it. The Var, anciently called the Varus, rises in the county of Nice, and after watering it empties itself into the Mediterranean. The language of the Piedmontese is a mixture of French and Italian. In this country are about 50 earldoms, 15 marquisates, a multitude of lordships, and 20 abbeys. Though the country be entirely popish, except some valleys inhabited by the Waldenses, the king reserves to himself the greatest part of the power in church affairs, which in many other places is given up to the pope, and the constitution *unigenitus* is here universally opposed. Towards the end of the last century, the French king persuaded the duke of Savoy to drive them out of the country; in consequence of which 200,000 of them retired to Germany, England, and Holland, and yet they are not all extirpated, though, as we have observed, they are obliged to have a Roman Catholic church in every parish.

Piedmont
Popish

Turin, the general residence of the king of Sardinia, to whom this principality belongs, is the chief city. See TURIN. The number of inhabitants, Mr Watkins says, in Piedmont and Savoy, amount to 2,695,727 souls, of which Turin contains about 77,000.

PIENES, a small island of Japan, over against the harbour of Saccai, is famed not only for the beauty of its walks, to which crowds of people resort from the city, but for a deity worshipped there, to which vast numbers of persons devote themselves. They go from his temple to the sea side, where they enter into a boat provided for the purpose; then, launching into the deep, they throw themselves overboard, loaded with stones, and sink to the bottom. The temple of that deity, which is called Canon, is very large and lofty, and so are many others in the city itself; one in particular, dedicated to the gods of other countries, is thought the finest in the whole empire.

PIEPOUDRE (*Court of*), the lowest, and at the same time the most expeditious, court of justice known to the law of England. It is called PIEPOUDRE, (*curia pedis pulverizati*), from the dusty feet of the suitors; or, according to Sir Edward Coke, because justice is there done as speedily as dust can fall from the foot: Upon the same principle that justice among the Jews was administered in the gate of the city, that the proceedings might be the more speedy, as well as public. But the etymology given us by a learned modern writer is much more ingenious and satisfactory; it being derived, according to him, from *piad pulbricus*,

5 A

pulbricus,

this part of Europe, that we have no doubt of their existence, nor of their being found hardy and serviceable as labourers.

(b) Each pound is valued in Piedmont at 18 s. Sterling. The little village of La Tour, in the valley of Luccerne, makes above 50,000 lb. annually, and the exports every year to the single city of Lyons amount to more than 160,000 l. Sterling.

Pier
||
Pierino.

publicaux, "a pedlar," in old French, and therefore signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record, incident to every fair and market; of which the steward of him who owns or has the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one. So that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer. The court hath cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of an action arose there. From this court a writ of error lies, in the nature of an appeal, to the courts at Westminster. The reason of its institution seems to have been, to do justice expeditiously among the variety of persons that resort from distant places to a fair or market; since it is probable, that no other inferior court might be able to serve its process, or execute its judgments, on both or perhaps either of the parties; and therefore, unless this court had been erected, the complainant must necessarily have resorted even in the first instance to some superior judicature.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortress to the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

PIERS of a Bridge. See BRIDGE.

PIERCEA. See RIVINIA.

PIERIA (anc. geog.), a district of Macedonia, contained between the mouths of the rivers Ludias and Peneus; extended by Strabo beyond the Ludias, to the river Axios on the north, and on the south no farther than the Aliacmon, along the west side of the Sinus Thermaicus.—Another *Pieria* of Syria, the north part of Seleucia, or the *Antiochena*, situated on the Sinus Mlicens, and lying next Cilicia to the north-west.

PIERIDES, in fabulous history, the daughters of Pierus a Macedonian prince, presuming to dispute with the muses for the prize of poetry, were turned into magpies. The name of *Pierides* was also given to the muses, from mount Pieres in Thessaly, which was consecrated to them; or, according to others, from Pierus, a Thessalian poet, who was the first who sacrificed to them. See PIERIS.

PIERINO DEL VAGA, an eminent Italian Painter, born of poor parents in Tuscany, about the year 1500. He was placed apprentice with a grocer in Florence, and got some instructions from the painters to whom he was sent with colours and pencils; but a painter named *Vaga* taking him to Rome, he was called *Del Vaga*, from living with him, his real name being *Buonarroti*. He studied anatomy with the sciences necessary for his profession; and had somewhat of every thing that was good in his compositions. After Raphael's death, he joined with Julio Romano and Francisco Penni to finish the works in the Vatican which were left imperfect by their common Master; and to confirm their friendship married Penni's sister. He gained the highest reputation by his performances in the palace of prince Doria in Genoa: but the multiplicity of his business, and the vivacity of his imagination, drained his spirits in the flower of his age; for he

died in the year 1547. Of all Raphael's disciples, Pierino kept the character of his master longest, *i. e.* his exterior character and manner of designing; for he fell very short of the fineness of Raphael's thinking. He had a particular genius for the decoration of places according to their customs. His invention in that kind of painting was full of ingenuity; grace and order are everywhere to be met with, and his dispositions, which are ordinary in his pictures, are wonderful in his ornaments: some of these he has made little, and some great, and placed them both with so much art, that they set off one another by comparison and contrast. His figures are disposed and designed according to Raphael's gusto; and if Raphael gave him at first some slight sketches of ornaments, as he did to Giovanni d'Udine, he executed them to admiration. The tapestries of the seven planets in seven pieces, which Pierino designed for Diana de Poitiers, and which were, when De Piles wrote, with Monsieur the first president at Paris, shows sufficiently what he was, and that the above character does not exceed the truth.

PIERIS (anc. geog.), a mountain which is thought to have given name to Peria of Macedonia; taking its name from Pierus a poet, who was the first that sacrificed to the Muses, thence called *Pierides*, if credit may be given to an ancient scholiast on Juvenal.

PIEKRE D'AUTOMNE is a French name, translated from the Chinese, of a medicinal stone, celebrated in the east for curing all disorders of the lungs. Many imagine it had its name on the autumn stone from its being only to be made at that season of the year; but it may certainly be made equally at all times. The Chinese chemists refer the various parts of the body to the several seasons of the year, and thus they refer the lungs to autumn. This is evident in their writings, and thus the stone for diseases of the lungs came to be called *autumn stone*. It is prepared as follows: They put 30 pints of the urine of a strong and healthy young man into a large iron pot, and set it over a gentle fire. When it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape oil. They then leave it on the fire till the whole is evaporated to a thick substance like black mud. It is then taken out of the pot, and laid on a flat iron to dry, so that it may be powdered very fine. This powder is moistened with fresh oil, and the mass is put into a double crucible, surrounded with coal, where it stands till it be thoroughly dried again. This is again powdered, and put into a china vessel, which being covered with silk cloth and a double paper, they pour on it boiling water, which makes its way, drop by drop, through these coverings, till so much is got in as is sufficient to reduce it to a paste. This paste is well mixed together in the vessel it is kept in, and this is put into a vessel of water, and the whole set over the fire. The matter thus becomes again dried in *banes marie*, and is then finished. *Observ. sur les Cout. de P'Asi*, p. 258.

PIERRE (St), is a large river in North America, scarcely inferior to the Rhine or the Danube, and navigable almost to its source. Together with many other large streams, it falls into the great river Mississippi.

PIERRE (St), or *St Peter's*, the capital of Martinico, was built in 1665, in order to overawe the multi-

Pieris,
Pierre,

Pierre
||
Piety.

Piety.

neers of the island who rebelled against its proprietors, the second West India company, who were at the same time the proprietors of all the French Antilles. It is situated on the western side of the island. The town extends along the shore, and a battery that commands the road is erected on the west side, which is washed by the river Royolan, or St Peter. The town is divided into three wards; the middle, which is properly St Peter's, begins at the fort, and runs westward to the battery of St Nicholas. Under the walls of the second ward ships at anchor ride more securely than under the fort, on which account this ward is called the *Anchorage*. The third ward, called the *Galery*, extends along the sea side from Fort St Peter to the Jesuits' River, and is the most populous part of the city. The houses of St Peter's ward are neat, commodious, and elegant, particularly those of the governor of the island, the intendant, and the other officers. The parish church of St Peter is a magnificent stone building which belonged to the Jesuits, with a noble front of the Doric order. The church of the Anchorage, which belongs to the Jacobine friars, is likewise of stone. It is a place of considerable trade, and is built with tolerable regularity. The houses are mostly constructed of a grey pumice-stone or lava, which is found on the strand; and the high street is, according to Dr Isert, above an English mile in length. It is supposed to contain about 2000 houses, and 30,000 inhabitants, including negroes. St Pierre, with the whole of the flourishing island of Martinico, was taken from the French in the month of March 1794, by the British land and sea forces under the command of Sir Charles Grey and Sir John Jervis, and may perhaps continue annexed to the British crown: 125 vessels loaded with the produce of the island, and of great value, were captured, 71 of which were in the harbour of St Pierre.

PIETISTS, a religious sect sprung up among the Protestants of Germany, seeming to be a kind of mean between the Quakers of England and the Quietists of the Romish church. They dispise all sorts of ecclesiastical polity, all school theology, and all forms and ceremonies, and give themselves up to contemplation and the mystic theology. Many gross errors are charged on the Pietists, in a book intitled *Manipulus Observationum Antipietisticarum*: but they have much of the air of polemical exaggeration, and are certainly not at all just. Indeed there are Pietists of various kinds: Some running into gross allusions, and carrying their errors to the overturning of a great part of the Christian doctrine, while others are only visionaries; and others are very honest and good, though perhaps misguided, people. They have been disgusted with the coldness and formality of other churches, and have thence become charmed with the fervent piety of the Pietists, and attached to their party, without giving into the grossest of their errors. See *Mosheim's Eccl. History*, vol. iv. p. 454.

PIETISTS, otherwise called the *Brethren and Sisters of the Pious and Christian Schools*, a society formed in the year 1678 by Nicholas Barre, and obliged by their engagements to devote themselves to the education of poor children of both sexes.

PIETOLA, anciently called *Andes*, is a place within two Italian miles of Mantua, famous for being the birth-place of Virgil.

PIETY, is a virtue which denotes veneration for the

Deity, and love and tenderness to our friends. This distinguished virtue, like many others, received among the Romans divine honours, and was made one of their gods. Atilius Glabrio first erected a temple to this divinity, which he did upon the spot on which a woman had fed with her own milk her aged father, who had been imprisoned by order of the senate, and deprived of all aliments. The story is well known, and is given at length in authors which are in the hands of every school-boy. See *Cicero d. d. p. 1.* and *Valerius Maximus*, 5. c. 4. and our article *Piety*, p. 238. col. 2d.

If piety was thus practised and thus honoured in Heathen antiquity, it surely ought not to be less so among Christians to whom its nature is better defined, and to the practice of which they have motives of greater cogency. A learned and elegant writer has said that the want of piety arises from the want of sensibility; and his observations and arguments are so just and so well expressed, that we cannot do better than transcribe them.

“It appears to me (says Dr Knox), that the mind of man, when it is free from natural defects and acquired corruption, feels no less a tendency to the indulgence of devotion than to virtuous love, or to any other of the more refined and elevated affections. But debauchery and excess contribute greatly to destroy all the susceptible delicacy with which nature usually furnishes the heart; and, in the general extinction of our better qualities, it is no wonder that so pure a sentiment as that of piety should be one of the first to expire.

“It is certain that the understanding may be improved in a knowledge of the world, and in the arts of succeeding in it, while the heart, or whatever constitutes the seat of the moral and sentimental feelings, is gradually receding from its proper and original perfection. Indeed experience seems to evince, that it is hardly possible to arrive at the character of a complete man of the world, without losing many of the most valuable sentiments of uncorrupted nature. A complete man of the world is an artificial being; he has discarded many of the native and laudable tendencies of his mind, and adopted a new system of objects and propensities of his own creation. These are commonly gross, coarse, sordid, selfish, and sensual. All, or either of these attributes, tend directly to blunt the sense of every thing liberal, enlarged, disinterested; of every thing which participates more of an intellectual than of a sensual nature. When the heart is tied down to the earth by lust and avarice, it is not extraordinary that the eye should be seldom lifted up to heaven. To the man who spends his Sunday (because he thinks the day fit for little else) in the counting house, in travelling, in the tavern, or in the brothel, those who go to church appear as fools, and the business they go upon as nonsense. He is callous to the feelings of devotion; but he is tremblingly alive to all that gratifies his senses or promotes his interest.

“It has been remarked of those writers who have attacked Christianity, and represented all religions merely as diversified modes of superstition, that they were indeed, for the most part men of a metaphysical and a disputatious turn of mind, but usually little distinguished for benignity and generosity. There was,

Piety.

amidst their pretensions to logical sagacity, a cloudiness of ideas, and a coldness of heart, which rendered them very unfit judges on a question in which the heart is chiefly interested; in which the language of nature is more expressive and convincing, than all the dreary subtleties of the dismal metaphysicians. Even the reasoning faculty, on which we so greatly value ourselves, may be perverted by excessive refinement; and there is an abstruse, but vain and foolish philosophy, which philosophizes us out of the noblest parts of our noble nature. One of those parts of us is our instinctive sense of religion, of which not one of those brutes which the philosophers most admire, and to whose rank they wish to reduce us, is found in the slightest degree to participate.

“Such philosophers may be called, in a double sense, the enemies of mankind. They not only endeavour to entice man from his duty, but to rob him of a most exalted and natural pleasure. Such, surely, is the pleasure of devotion. For when the soul rises above this little orb, and pours its adorations at the throne of celestial Majesty, the holy fervour which it feels is itself a rapturous delight. Neither is this a declamatory representation, but a truth felt and acknowledged by all the sons of men; except those who have been defective in sensibility, or who hoped to gratify the pride or the malignity of their hearts by singular and pernicious speculation.

“Indeed all disputations, controversial and metaphysical writings on the subject of religion, are unfavourable to genuine piety. We do not find that the most renowned polemics in the church militant were at all more attentive than others to the common offices of religion, or that they were actuated by any peculiar degree of devotion. The truth is their religion centered in their heads, whereas its natural region is the heart. The heart! confined, alas! in colleges or libraries, unacquainted with all the tender charities of husband, father, brother, friend; some of them have almost forgotten that they possess a heart. It has long ceased to beat with the pulsations of love and sympathy, and has been engrossed by pride in conquering an adversary in the syllogistic combat, or by impotent anger on a defeat. With such habits, and so defective a system of feelings, can we expect that a doctor of the Sorbonne, or the disputing professor of divinity, should ever feel the pure flame of piety that glowed in the bosoms of Mrs Rowe, Mrs Talbot, or Mr Nelson?

“It is however certain that a devotional taste and habit are very desirable in themselves exclusive of their effects in meliorating the morals and disposition, and promoting present and future felicity. They add dignity, pleasure, and security to any age: but to old age they are the most becoming grace, the most substantial support, and the sweetest comfort. In order to preserve them, it will be necessary to preserve our sensibility; and nothing will contribute so much to this purpose as a life of temperance, innocence, and simplicity.”

Of piety, as it denotes love and tenderness to our friends, there have been many distinguished instances both in ancient and modern times. See *FILIAL Piety*, *FRATERNAL* and *PARENTAL Affection*, &c.

The following example of filial piety in China, ta-

ken from P. Du Halde's description of that country, will not we trust be disagreeable to our readers. “In the commencement of the dynasty of the Tang, Lou-tao-fong, who was disaffected to the government, being accused of a fault, which touched his life, obtained leave from those who had him in custody, to perform the duties of the Tao to one of his deceased friends. He managed matters so well that giving his keepers the slip, he fled to the house of Lou Nan-kin, with whom he had a friendship, and there hid himself. Lou Nan-kin, notwithstanding the strict search that was made, and the severity of the court against those who conceal prisoners that have escaped, would not betray his friend. However, the thing coming to be discovered, Lou Nan-kin was imprisoned; and they were just on the point of proceeding against him, when his younger brother presenting himself before the judge, *It is I, Sir, said he, who have hidden the prisoner; it is I who ought to die, and not my elder brother.* The eldest maintained on the contrary, that his younger brother accused himself wrongfully, and was not at all culpable. The judge, who was a person of great sagacity, sifted both parties so effectually, that he not only discovered that the younger brother was innocent, but even made him confess it himself: *It is true, Sir, said the younger all in tears, I have accused myself falsely; but I have very strong reasons for so doing. My mother has been dead for some time, and her corps is not yet buried; I have a sister also who is marriageable, but is not yet disposed of: these things which my brother is capable of managing I am not, and therefore desire to die in his stead. Kneel safe to admit my testimony.* The commissioner gave an account of the whole affair to the court, and the emperor at his solicitation pardoned the criminal.”

Guinea Pig. See MUS.

Pig of lead, the eighth part of a fother, amounting to 250 pounds weight.

PIGANIOL DE LA FORCE (John Aymar de), a native of Auvergne, of a noble family, applied himself with ardour to the study of geography, and of the history of France. With the view of improving himself in this study he travelled, into different provinces; and, in the course of his travels, made some important observations on the natural history, the commerce, the civil and ecclesiastical government of each province. These observations were of great use to him in compiling the works he has left behind him, of which the chief are, 1. An Historical and Geographical Description of France; the largest edition of which is that of 1753, in 15 vol. 12mo. It is the best work which has hitherto appeared upon that subject, though it contains a great number of inaccuracies and even errors. 2 A description of Paris, in 10 vol. 12mo; a work equally entertaining and instructive, and much more complete than the description given by Germain Brice: besides, it is written with an elegant simplicity. He published an abridgement of it in 2 vol. 12mo. 3. A description of the Castle and Park of Versailles, Marly, &c. in 2 vol. 12mo: it is very amusing, and pretty well executed. Piganol had also a concern with Abbé Nadal in the Journal of Trevoux. He died at Paris in February 1753, at the age of 80 years. This learned man was as much to be respected for his manners as for his talents. To a profound and varied knowledge

PIGEON, in ornithology. See **COLUMBA**.

Pigeon-House is a house erected full of holes within for the keeping, breeding, &c. of pigeons, otherwise called a *dove cote*.

Any lord of manor in England, may build a pigeon-house on his land, but a tenant cannot do it without the lord's licence. When persons shoot at or kill pigeons within a certain distance of the pigeon-house, they are liable to pay a forfeiture.

In order to erect a pigeon-house, to advantage, it will be necessary in the first place, to pitch upon a convenient situation; of which none is more proper than the middle of a spacious court-yard, because pigeons are naturally of a timorous disposition, and the least noise they hear frightens them. With regard to the size of the pigeon-house, it must depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too little; and as to its form, the round should be preferred to the square ones, because rats cannot so easily come at them in the former as in the latter. It is also much more commodious; because you may, by means of a ladder turning upon an axis, easily visit all the nests in the house without the least difficulty; which cannot so easily be done in a square house. In order to hinder rats from climbing up the outside of the pigeon house, the wall should be covered with tin plates to a certain height, about a foot and a half will be sufficient; but they should project out three or four inches at the top, to prevent their clambering any higher.

The pigeon-house should be placed at no great distance from water, that the pigeons may carry it to their young ones; and their carrying it in their bills will warm it, and render it more wholesome in cold weather. The boards that cover the pigeon-house should be well joined together, so that no rain may penetrate through it: and the whole building should be covered with hard plaster, and white washed within and without, white being the most pleasing colour to pigeons. There must be no window, or other opening in the pigeon-house to the eastward; these should always face the south, for pigeons are very fond of the sun, especially in winter.

The nests or covers in a pigeon-house should consist of square holes made in the walls of a size sufficient to admit the cock and hen to stand in them. The first range of these nests should not be less than four feet from the ground, that the wall underneath being smooth, the rats may not be able to reach them. These nests should be placed in quincunx-order, and not directly over one-another. Nor must they be continued any higher than within three feet of the top of the wall: and the upper row should be covered with a board projecting a considerable distance from the wall, for fear the rats should find means to climb the outside of the house.

M. Duhamel thinks that pigeons neither feed upon the green corn, nor have bills strong enough to search for its seeds in the earth; but only pick up the grains that are not covered, which would infallibly become the prey of other animals, or be dried up by the sun. "From the time of the sprouting of the corn, says he, pigeons live chiefly upon the feeds of wild uncultivated

plants, and therefore lessen considerably the quantity of weeds that would otherwise spring up; as will appear from a just estimate of the quantity of grain necessary to feed all the pigeons of a well stocked dove-house." But Mr Worlidge and Mr Lisle allege facts, in support of the contrary opinion. The latter relates, that a farmer in his neighbourhood assured him he had known an acre sowed with peas, and rain coming on so that they could not be harrowed in, every peck was fetched away in half a day's time by pigeons: and the former says, "It is to be observed, that where the flight of pigeons falls, there they fill themselves and away, and return again where they first rose, and so proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground they know how to find it. I have seen them lie so much upon a piece of about two or three acres sown with peas, that they devoured at least three parts in four of the seed, which I am sure, could not be all above the surface of the ground. That their smelling is their principal director, I have observed; having sown a small plat of peas in my garden, near a pigeon-house, and covered them so well that not a pea appeared above ground. In a few days, a parcel of pigeons were hard at work in discovering this hidden treasure; and in a few days more I had not above two or three peas left out of about two quarts that were planted; for what they could not find before, they found when the buds appeared, notwithstanding they were hoed in, and well covered. Their smelling alone directed them as I supposed, because they followed the ranges exactly. The injury they do at harvest on the peas, vetches, &c. is such that we may rank them among the greatest enemies the poor husbandman meets withal; and the greater because he may not erect a pigeon house, whereby to have a share of his own spoils; none but the rich being allowed this privilege, and so severe a law being also made to protect these winged thieves, that a man cannot encounter them, even in defence of his own property. You have therefore no remedy against them, but to affright them away by noises or such like. You may, indeed, shoot at them; but you must not kill them; or you may, if you can, take them in a net, cut off their tails, and let them go; by which means you will impound them: for when they are in their houses, they cannot bolt or fly out of the tops of them but by the strength of their tails; after the thus weakening of which, they remain prisoners at home."

Mr Worlidge's impounding the pigeons reminds us of a humorous story of a gentleman who, upon a neighbouring farmer's complaining to him, that his pigeons were a great nuisance to his land, and did find mischief to his corn, replied, jokingly, Pound them, if you catch them trespassing. The farmer, improving the hint, steeped a parcel of peas in an infusion of *coccus indicus*, or some other intoxicating drug, and strewed them upon his grounds. The pigeons swallowed them, and soon remained motionless on the field: upon which the farmer threw a net over them, inclosed them in it, and carried them to an empty barn, from whence he sent the gentleman word that he had followed his directions with regard to the pounding of his pigeons and desired him to come and release them.

Carrier-Pigeon. See *CARRIER-Pigeon* and **COLUMBA**.

Pigeon.

Pigeon.

PIGÉON (Peter Charles Francis), curate of St Peter du Regard, in the diocese of Bayeux, was one of the priests lately belonging to the king's house at Winchester. He was born in Lower Normandy, of honest and virtuous parents, and of a decent fortune. His inclinations early led him to embrace the ecclesiastical state, from which neither the solicitations of his friends, nor the prospect of a more ample fortune on the death of his elder brother, could withdraw him. Several of his schoolfellows and masters, who are now resident in the king's house at Winchester, bear the most ample testimony to his assiduity, regularity, piety, and the sweetness of his disposition, during the whole course of his education. The sweetness of temper, in particular, was so remarkable, and so clearly depicted on his countenance, as to have gained him the esteem and affection of such of the inhabitants of Winchester as by any means had become acquainted with him. He was seven years employed in quality of vicar, or, as we should call it *curate*, of a large parish in the diocese of Sees, where his virtues and talents had ample scope for exertion. His practice was to rise at five o'clock every morning, and to spend the whole time till noon (the usual time of dining for persons in his station) in prayer and study. The rest of the day, till evening be devoted to visiting the sick, and other exterior duties of his function. In 1789, the year of the French Revolution, M. Pigeon was promoted to a curacy, or rather a rectory, in the diocese of Bayeux, called the *parish of St Peter du Regard*, near the town of Condé sur Noireau. It was easy for him to gain the good-will and the protection of his parishioners; but a Jacobin club in the above mentioned town seemed to have no other subject to deliberate upon than the various ways of harassing and persecuting M. Pigeon and certain other priests in the neighbourhood, who had from motives of conscience refused the famous civic oath. It would be tedious to relate the many cruelties which were at different times exercised upon him, and the imminent danger of losing his life to which he was exposed, by the blows that were inflicted on him, by his being thrown into water, and being obliged to wander in woods and other solitary places, without any food or place to lay his head, in order to avoid his persecutors. We may form some judgment of the spirit of his persecutors from the following circumstance. Being disappointed on a particular occasion in the search they were making after M. Pigeon, with the view of amusing themselves with his sufferings, they made themselves amends by seizing his mother, a respectable lady of 74 years of age, and his two sisters, whom they placed upon asses with their faces turned backwards, obliging them in derision to hold the tails of these animals. Thus they were conducted in pain and ignominy throughout the whole town of Conde, for no other alleged crime except being the nearest relations of M. Pigeon. At length the decree for transporting all the ecclesiastics arrived; and this gentleman, with several others, after having been stripped of all their money, was shipped from Port Bessin, and landed at Portsmouth, where he was shortly after received into the establishment at Foxton, and upon that being dissolved in order to make room, for prisoners of war, into the king's house at Winchester. Being of a studious turn, he was accustomed, as many of his brethren also

were, to betake himself to the neighbouring lanes and thickets for the sake of greater solitude. With this view having about ten o'clock in the morning, Aug. 28. 1793, retired to a certain little valley, on the north-east side of a place called *Oran's Arbour*, the same place where the county elections for Hampshire are held, he was there found, between three and four o'clock in the afternoon, murdered, with the upper part of his skull absolutely broken from the lower part, and a large hedge-stake, covered with blood, lying by him, as were the papers in which he had been transcribing a manuscript sermon, with the hearing of which he had been much edified, and the sermon itself which he was copying, together with his pen, imbrued in blood. His watch was carried away, though part of the chain, which had by some means been broken, was left behind. He was writing the word *paraisé*, the last letters of which remained unwritten when the fatal blow was given him, which appears evidently to have been discharged upon him from a gap in a hedge which was immediately behind him. At first the suspicion of this cruel murder fell upon the French democrats, who, to the number of 200, are prisoners of war, at the neighbouring town of Alresford, as one of that number, who had broken his parole, had about three weeks before, been taken up in Winchester, and both there and at Alresford had repeatedly threatened to murder his uncle, a priest, whom he understood to be then at Winchester, not without fervent wishes of having it in his power to murder the whole establishment, consisting of more than 600 persons. However, as no French prisoner was seen that day in the neighbourhood of Winchester, as none of them were known to have left Alresford, it is evidently reasonable to acquiesce in the verdict of the coroner; namely, that the murder was committed by a person or persons, unknown. The most noble marquis of Buckingham, whose munificence and kindness to those conscientious exiles, the emigrant French clergy, can only be conceived by those who have been witnesses of the same, with the truly respectable corps of the Buckinghamshire militia, then quartered at Winchester, joined in paying the last mark of respect to the unfortunate deceased, by attending his funeral, which was performed at the Roman Catholic burying-ground, called *St James's* near the said city, on Saturday August 29. He was just 38 years of age when he was murdered.

PIGMENTS, preparations used by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours. See *COLOUR Making*, and *DYEING*.

PIGNEROL, is a town of Italy in the province of Piedmont, in E. Long. 7. 15. Lat. 44. 45, situated on the river Chizon, 10 miles south-west of Turin, at the foot of the Alps, and the confines of Dauphiny. The town is small, but populous, and extremely well fortified by the king of Sardinia, since the treaty of Utrecht. It is defended by a citadel, on the top of the mountain, near which is the castle of Perouse, which was built at the entrance of the valley of that name.

PIGNUT, or *Earthnut*. See **BUNION**

PIGUS, in ichthyology, is the name of a species of leather mouthed fish, very much resembling the nature of the common carp; being of the same shape and size, and its eyes, fins, and fleshy palate, exactly the same from the gills to the tail there is a crooked dotted line; the

Pigeon
||
Pigus.

Pi-hahiroth
 Pike.

 the back and sides are bluish, and the belly reddish. It is covered with large scales; from the middle of each of which their ribs a fine, pellucid, prickle, which is very sharp. It is an excellent fish for the table, being perhaps preferable to the carp: and it is in season in the months of March and April. It is caught in lakes in some parts of Italy, and is mentioned by Pliny, tho' without a name. Artedi says it is a species of cyprinus, and he calls it the *cyprinus*, called *pyelo* and *pygus*.

PI-HAHIROTH, (Moses); understood to be a mouth or narrow pass between two mountains, called *Chiroth*, or *Eiroth*, and lying not far from the bottom of the western coast of the Arabian gulf; before which mouth the children of Israel encamped, just before their entering th Red Sea, (Wells).

PISSKER, in ichthyology, is a fish of the mussela kind, commonly called the *sessile mussela*, or *sessile fish*. They are generally found as long as an ordinary man's hand is broad, and as thick as one's finger; but they sometimes grow much longer: the back is of grey with a number of spots and transverse streaks, partly black and partly blue; the belly is yellow, and spotted with red, white, and black; the white are the larger, the others look as if they were made with the point of a needle; and there is on each of the sides a longitudinal black and white line. There are some fleshy excrescences at the mouth, which are expanded in swimming; and when out of the water, they are contracted. These fishes run into caverns of the earth, in the sides of rivers, in marshy places, and penetrate a great way, and are often dug up at a distance from waters. Often, when the waters of brooks and rivers swell beyond their banks, and again cover them, they make their way out of the earth into the water; and when it deserts them, they are often left in vast numbers upon the ground and become a prey to swine. It is thought to be much of the same kind with the *sigum* fish; and it is indeed possible that the *pæcillia* of Schonefeldt is the same.

PIKE, in ichthyology. See *Esox*.

The pike never swims in shoals as most other fish do, but always lies alone; and is so bold and ravenous, that he will seize upon almost any thing less than himself. Of the ravenous nature of this fish we shall give the following instances. At Rycott in Oxfordshire, in the year 1749, in a moat surrounding the earl of Abingdon's seat, there was a jack or pike of such a monstrous size, that it had destroyed young swans feathers and all. An old cobb swan having hatched five young, ones after another was lost till four were gone. At length an under gardener saw the fish seize the fifth. The old one fought him with her beak, and with the assistance of the gardener; released it although he had got it under water. In the year 1765 a large pike was caught in the river Ouze, which weighed upwards of 28 pounds, and was sold for a guinea. On gutting the fish, a watch with a black ribbon and two steel seals were found in its stomach, which by the maker's name, &c. was found to belong to a person who had been drowned about six weeks before. This fish breeds but once in a year, which is in March. It is found in almost all fresh waters; but is very different in goodness, according to the nature of the places where it lives. The finest pike are those which feed in clear rivers; those in ponds and meres are inferior to

these, and the worst of all are those of the fen ditches. They are very plentiful in these last places, where the water is foul and coloured; and their food such as frogs and the like, very plentiful, but very coarse; so that they grow large, but are yellowish and high bellied, and differ greatly from those which live in the clearer waters.

The fishermen have two principal ways of catching the pike: by the ledger, and by the walking-bait.

The ledger bait is fixed in one certain place, and may continue while the angler is absent. This must be a live bait, a fish or frog: and among fish, the dace, roach, and gudgeon, are the best; of frogs, the only caution is to choose the largest and yellowest that can be met with. If the bait be a fish, the hook is to be stuck through the upper lip, and the line must be 14 yards at least in length; the other end of this is to be tied to a bough of a tree, or to a stick driven into the ground near the pikes's haunt and all the line wound round a forked stick, except about half a yard. The bait will by this means keep playing so much under water, and the pike will soon lay hold of it.

If the bait be a frog then the arming wire of the hook should be put in at the mouth, and out at the side; and with a needle and some strong silk, the hinder-leg of one side is to be fastened by one stitch to the wire arming of the hook. The pike will soon seize this, and must have line enough to give him leave to get to his haunt and poach the bait.

The trolling for pike is a pleasant method also of taking them: on this a dead bait serves, and none is so proper as a gudgeon.

This is to be pulled about in the water till the pike seizes it; and then it is to have line enough, and time to swallow it: the hook is small for this sport, and has a smooth piece of lead fixed at its end to sink the bait; and the line is very long, and runs through a ring at the end of the rod, which must not be too slender at top.

The art of feeding pike, so as to make them very fat, is the giving them eels; and without this it is not to be done under a very long time; otherwise perch, while small and their prickly fins tender, are the best food for them. Bream put into a pike pond are a very proper food: they will breed freely, and their young ones make excellent food for the pike, who will take care that they shall not increase over much. The numerous shoals of roaches and ruds, which are continually changing place, and often in floods get into the pike's quarters, are food for them for a long time.

Pike, when used to be fed by hand, will come up to the very shore, and take the food that is given them out of the fingers of the feeder. It is wonderful to see with what courage they will do this, after a while practising; and it is a very diverting sight when there are several of them nearly of the same size, to see what striving and fighting there will be for the best bits when they are thrown in. The most convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the ossal of the feedings will all lie in one place, and the deep water will serve for a place to retire into and rest in, and will be always clean and in order.

Carp will be fed in the same manner as pike; and though by nature a fish as remarkably shy and timor-

Pike,
Pila.

rous as the pike is bold and fearless, yet by custom they will come to take their food out of the person's hand; and will, like the pike, quarrel among one another for the nicest bits.

PIKE, in war, an offensive weapon, consisting of a wooden shaft, 12 or 14 feet long, with a flat steel head, pointed, called the *spear*. This weapon was long in use among the infantry; but now the bayonet, which is fixed on the muzzle of the firelock, is substituted in its stead. It is still used by some of the officers of infantry, under the name of *sponton*. The Macedonian phalanx was a battalion of pikemen. See PHALANX.

PILA MARINA, or the *sea-ball*, in natural history, is the name of a substance very common on the shores of the Mediterranean, and elsewhere. It is generally found in the form of a ball about the size of the balls of horse-dung, and composed of a variety of fibrillæ irregularly complicated. Various conjectures have been given of its origin by different authors. John Bauhine tells us, that it consists of small hairy fibres and straws, such as are found about the sea plant called *alga vitriariorum*; but he does not ascertain what plant it owes its origin to. Imperatus imagined it consisted of the cruvæ both of vegetable and animal bodies. Mercatus is doubtful whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the sea water, or whether it be not the workmanship of some sort of beetle living about the sea shore, and analogous to our common dung beetle's ball, which it elaborates from dung for the reception of its progeny. Schreckius says it is composed of the filaments of some plant of the reed kind: and Welchius supposes it is composed of the pappous part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus; and others think it that of the phoca or sea calf. Klein, who had thoroughly and minutely examined the bodies themselves, and also what authors had conjectured concerning them, thinks that they are wholly owing to, and entirely composed of, the capillaments which the leaves, growing to the woody stalk of the *alga vitriariorum*, have when they wither and decay. These leaves, in their natural state, are as thick as a wheat straw, and they are placed so thick about the tops and extremities of the stalks, that they enfold, embrace, and lie one over another; and from the middle of these clusters of leaves, and indeed from the woody substance of the plant itself, there arise several other very long flat, smooth, and brittle leaves. These are usually four from each tuft of the other leaves; and they have ever a common vagina, which is membranaceous and very thin. This is the style of the plant, and the *pila marina*, appears to be a cluster of the fibres of the leaves of this plant, which cover the whole stalk, divided into their constituent fibres; and by the motion of the waves first broken and worn into short threads, and afterwards wound up together into a roundish or longish ball.

PILA, was a ball made in a different manner according to the different games in which it was to be used. Playing at ball was very common amongst the Romans of the first distinction, and was looked upon as a manly exercise, which contributed both to amusement and health. The pila was of four sorts: 1st, *Follis* or *baloon*; 2d, *Pila Trigonalis*; 3d, *Pila Paganica*; 4th, *Hypostum*. All these come under the general

name of pila. For the manner of playing with each of them, see the articles FOLLIS, TRIGONALIS.

PILASTER, in architecture. See there, r.^o 50, &c.

PILATE, or PONTIUS PILATE, was governor of Judea when our Lord was crucified. Of his family or country we know but little, though it is believed that he was of Rome, or at least of Italy. He was sent to govern Judea in the room of Grains, in the year 26 or 27 of the vulgar era, and governed this province for ten years, from the 12th or 13th year of Tiberius to the 22d or 23d. He is represented both by Philo and Josephus as a man of an impetuous and obstinate temper, and as a judge who used to sell justice, and to pronounce any sentence that was desired, provided he was paid for it. The same authors make mention of his rapines, his injuries, his murders, the torments that he inflicted upon the innocent, and the persons he put to death without any form of process. Philo, in particular, describes him as a man that exercised an excessive cruelty during the whole time of his government, who disturbed the repose of Judea, and gave occasion to the troubles and revolt that followed after. St Luke (xiii. 1, 2, &c.) acquaints us, that Pilate had mingled the blood of the Galileans with their sacrifices; and that the matter having been related to Jesus Christ, he said, "Think you that these Galileans were greater sinners than other Galileans because they suffered this calamity. I tell you nay; and if you do not repent, you shall all perish in like manner. It is unknown upon what occasion Pilate caused these Galileans to be slain in the temple while they were sacrificing; for this is the meaning of that expression of mingling their blood with their sacrifices. Some think they were disciples of Judas the Gaulonite, who taught that the Jews ought not to pay tribute to foreign princes; and that Pilate had put some of them to death even in the temple; but there is no proof of this fact. Others think that these Galileans were Samaritans, whom Pilate cut to pieces in the village of Tirataba †, as they were preparing to go up to mount Gerizim, where a certain impostor had promised to discover treasures to them; but this event did not happen before the year 35 of the common era, and consequently two years after the death of Jesus Christ. At the time of our Saviour's passion, Pilate made some endeavours to deliver him out of the hands of the Jews. He knew they had delivered him up, and pursued his life with so much violence, only out of malice and envy (Matt. xxvii. 18.) His wife also, who had been disturbed the night before with frightful dreams, sent to tell him she desired him not to meddle in the affair of that just person (ib. 19.) He attempted to appease the wrath of the Jews, and to give them some satisfaction, by whipping Jesus Christ (John xix. 1. Matth. xxvii. 26.) He tried to take him out of their hands, by proposing to deliver him or Barrabas, on the day of the festival of the passover. Lastly, he had a mind to discharge himself from pronouncing judgment against him, by sending him to Herod king of Galilee (Luke xxiii. 7, 8.) When he saw all this would not satisfy the Jews, and that they even threatened him in some manner, saying he could be no friend to the emperor if he let him go (John xix. 12, 15.), he caused water to be brought, washed his hands before

Ant. lib.
18. c. 5.

Pilate. all the people, and publicly declared himself innocent of the blood of that just person (Matt. xxvii. 23, 24.); yet at the same time he delivered him up to his soldiers, that they might crucify him. This was enough to justify Jesus Christ, as Calmet observes, and to show that he held him as innocent; but it was not enough to vindicate the conscience and integrity of a judge, whose duty it was as well to assert the cause of oppressed innocence as to punish the guilty and criminal. He ordered to be put over our Saviour's cross, as it were, an abstract of his sentence, and the motive of his condemnation (John xix. 19.), *Jesus of Nazareth, king of the Jews*, which was written in Latin, Greek, and Hebrew. Some of the Jews found fault with it, and remonstrated to Pilate that he ought to have written *Jesus of Nazareth, who pretended to be king of the Jews*. But Pilate could not be prevailed with to alter it, and gave them this peremptory answer, *That what he had written he had written*.

Towards evening, he was applied to for leave to take down the bodies from the cross, that they might not continue there the following day, which was the passover and the sabbath-day (John xix. 31.) This he allowed, and granted the body of Jesus to Joseph of Arimathea, that he might pay his last duties to it, (ib. 33.) Lastly, when the priests, who had solicited the death of our Saviour, came to desire him to set a watch about the sepulchre, for fear his disciples should steal him away by night, he answered them, that they had a guard, and might place them there themselves (Matt. xxvii. 65.) This is the substance of what the gospel tells us concerning Pilate.

Justin Martyr, Tertullian, Eusebius, and after them several others both ancient and modern, assure us, that it was formerly the custom for Roman magistrates to prepare copies of all verbal processes and judicial acts which they passed in their several provinces, and to send them to the emperor. And Pilate, in compliance to this custom, having sent word to Tiberius of what had passed relating to Jesus Christ, the emperor wrote an account of it to the senate, in a manner that gave reason to judge that he thought favourably of the religion of Jesus Christ, and showed that he would be willing they should decree divine honours to him. But the senate was not of the same opinion, and so the matter was dropped. It appears by what Justin says of these acts, that the miracles of Jesus Christ were mentioned there, and even that the soldiers had divided his garments among them. Eusebius insinuates that they spoke of his resurrection and ascension. Tertullian and Justin refer to these acts with so much confidence as would make one believe they had them in their hands. However, neither Eusebius nor St Jerome, who were both inquisitive, understanding persons, nor any other author that wrote afterwards, seem to have seen them, at least not the true and original acts; for as to what we have now in great number, they are not authentic, being neither ancient nor uniform. There are also some pretended letters of Pilate to Tiberius, giving a history of our Saviour, but they are universally allowed to be spurious.

Pilate being a man that, by his excessive cruelties and rapine, had disturbed the peace of Judea during the whole time of his government, was at length deposed by Vitellius the proconsul of Syria, in the 36th

year of Jesus Christ, and sent to Rome to give an account of his conduct to the emperor. But though Tiberius died before Pilate arrived at Rome, yet his successor Caligula banished him to Vienne in Gaul, where he was reduced to such extremity that he killed himself with his own hands. The evangelists call him governor, though in reality he was no more than procurator of Judea, not only because governor was a name of general use, but because Pilate in effect acted as one, by taking upon him to judge in criminal matters; as his predecessors had done, and other procurators in the small provinces of the empire where there was no proconsul, constantly did. See *Calmet's Dictionary*, *Eclard's Ecclesiastical History*, and *Beausobre's Annot.*

With regard to Pilate's wife, the general tradition is, that she was named Claudia Procula or Procula; and in relation to her dream, some are of opinion that as she had intelligence of our Lord's apprehension, and knew by his character that he was a righteous person, her imagination, being struck with these ideas, did naturally produce the dream we read of; but others think that this dream was sent providentially upon her, for the clearer manifestation of our Lord's innocence.

PILATRE DU ROSIER (Francis), was born at Metz the 30th of March 1756. He was first apprentice to an apothecary there, and afterwards went to Paris in quest of farther improvement. He applied himself to the study of natural history and of natural philosophy, and had already acquired some reputation, when the discovery of M. de Montgolfier had just astonished the learned world. On the 25th of October 1783, he attempted an aerial voyage with the Marquis of Arlande. He performed several other excursions in this way with brilliant success, in the presence of the royal family of France, of the king of Sweden, and of Prince Henry of Prussia. He then resolved to pass into England by means of his aerial vehicle, and for that purpose he repaired to Boulogne, whence he rose about 7 o'clock in the morning of the 15th June 1785; but in half an hour after he set out, the balloon took fire, and the aeronaut, with his companion M. Romaine, were crushed to death by the fall of that machine, which was more ingenious, perhaps, than useful*. Pilatre's social virtues and courage, which were very distinguished, heightened the regret of his friends for his loss. His merit as a chemist, and his experiments as an aeronaut, procured him some precunary reward, and some public appointments. He had a pension from the King, was intendant of Monsieur's cabinets of natural philosophy, chemistry, and natural history, professor of natural philosophy, a member of several academies, and principal director of Monsieur's museum.

PILCHARD, in ichthyology, a fish which has a general likeness to the herring, but differs in some particulars very essential. The body of the pilchard is less compressed than that of the herring, being thicker and rounder: the nose is shorter in proportion, and turns up; the under jaw is shorter. The back is more elevated; the belly less sharp. The dorsal fin of the pilchard is placed exactly in the center of gravity, so that when taken up by it, the body preserves an equilibrium, whereas that of the herring dips at the head. The scales of the pilchard adhere very closely, whereas those of the herring very easily drop off. The pil-

Pilate,
Pilchard.

station,
p^o 34.

Pilchard, Pile. chard is in general less than the herring; but it is fatter, or more full of oil.

The pilchard appears in vast shoals off the Cornish coasts about the middle of July, disappearing the beginning of winter, yet sometimes a few return again after Christmas. Their winter retreat is the same with that of the herring, and their motives for migrating the same. They affect, during summer, a warmer latitude; for they are not found in any quantities on any of the English coasts except those of Cornwall, that is to say, from Fowey harbour to the Scilly isles, between which places the shoals keep shifting for some weeks. The approach of the pilchard is known by much the same signs as those that indicate the arrival of the herring. Persons, called in Cornwall *buers*, are placed on the cliffs, to point to the boats stationed off the land the course of the fish. By the 1st of James I. c. 23, fishermen are empowered to go on the grounds of others to hue, without being liable to actions of trespass, which before occasioned frequent law-suits.

The emoluments that accrue to the inhabitants of that country are great, and are best expressed in the words of Dr W. Borlase, in his *Account of the Pilchard Fishery*. "It employs a great number of men on the sea, training them thereby to naval affairs; employs men, women, and children, at land, in salting, pressing, washing, and cleaning, in making boats, nets, ropes, casks, and all the trades depending on their construction and sale. The poor are fed with the offals of the captures; the land with the refuse of the fish and salt; the merchant finds the gains of commission and honest commerce; the fisherman, the gains of the fish. Ships are often freighted hither with salt, and into foreign countries with the fish, carrying off at the same time part of our tin. The usual number of hogheads of fish exported each year, for ten years, from 1747 to 1756 inclusive, from, the four ports of Fowey, Falmouth, Penzance, and St Ives, in all amounts to 29,794; since it appears that Fowey has exported yearly 1732 hogheads; Falmouth, 14,631 hogheads and two-thirds; Penzance and Mounts-Bay, 12,149 hogheads and one-third; St Ives, 1282 hogheads. Every hoghead for ten years last past, together with the bounty allowed for each when exported, and the oil made out of each, has amounted, one year with another at an average, to the price of L. 1 : 13 : 3; so that the cash paid for pilchards exported has, at a medium, annually amounted to the sum of L. 49,532, 10s." The numbers that are taken at one shooting out of the nets is amazingly great. Mt Pennant says, that Dr Borlase assured him, that on the 5th of October 1767, there were at one time inclosed in St Ives's Bay 7000 hogheads, each hoghead containing 35,000 fish, in all 245,000,000.

PILE, in heraldry, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the shield.

PILL, among the Greeks and Romans, was a pyramid built of wood, whereon were laid the bodies of the deceased to be burnt. It was partly in the form of an altar, and differed in height according to the quality of the person to be consumed. Probably it might originally be considered as an altar, on which the dead were consumed as a burnt-offering to the in-

fernal deities. The trees made use of in the erection of a funeral pile were such as abounded in pitch or rosin, as being most combustible; if they used any other wood, it was split that it might the more easily catch fire. Round the pile were placed cypress boughs to hinder the noisome smell. See **FUNERAL**.

PILE, in building, is used for a large stake rammed into the ground in the bottom of rivers, or in marshy land, for a foundation to build upon.

Pile is also used among architects for a mass of building.

PILE, in coinage, denotes a kind of puncheon, which, in the old way of coining with the hammer, contained the arms or other figure and inscription to be struck on the coin. See **COINAGE**.

Accordingly we still call the arms side of a piece of money the *pile*, and the head the *cross*; because in ancient coin, a cross usually took the place of the head in ours.

PILE-Engine, a very curious machine invented by Mr Vauloue for driving the piles of Westminster-bridge. It is represented Plate CCCXCIII. A is a great upright shaft or axle, on which are the great wheel B, and the drum C, turned by horses joined to the bars S, S. The wheel B turns the trundle X, on the top of whose axis is the fly O, which serves to regulate the motion, and also to act against the horses, and to keep them from falling when the heavy ram Q is discharged to drive the pile P down into the mud in the bottom of the river. The drum C is loose upon the shaft A, but is locked to the wheel B by the bolt Y. On this drum the great rope HH is wound; one end of the rope being fixed to the drum, and the other to the follower G, to which it is conveyed over the pulleys I and K. In the follower G is contained the tongs F, that takes hold of the ram Q by the staple R, for drawing it up. D is a spiral or fusey fixed to the drum, on which is wound the small rope T that goes over the pulley U, under the pulley V, and is fastened to the top of the frame at 7. To the pulley-block V is hung the counterpoise W, which hinders the follower T from accelerating as it goes down to take hold of the ram; for as the follower tends to acquire velocity in its descent, the line T winds downwards upon the fusey, on a larger and larger radius, by which means the counterpoise W acts stronger and stronger against it; and so allows it to come down with only a moderate and uniform velocity. The bolt Y locks the drum to the great wheel, being pushed upward by the small lever 2, which goes through a mortise in the shaft A, turns upon a pin in the bar 3, fixed to the great wheel B, and has a weight 4, which always tends to push up the bolt Y through the wheel into the drum. L is the great lever turning on the axis m, and resting upon the forcing bar 5, 5, which goes through a hollow in the shaft A, and bears up the little lever 2.

By the horses going round, the great rope H is wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, until the tongs come between the inclined planes E; which, by shutting the tongs at the top, opens it at the foot, and discharges the ram which falls down between the guides *bb* upon the pile P, and drives it by a few strokes as far into the mud as it will go; after which, the top part is sawed off close to the mud by an engine for that purpose.

Immediately

Pile. Immediately after the ram is discharged, the piece 6 upon the follower G takes hold of the ropes *aa*, which raise the end of the lever L, and cause its end N to descend and press down the forcing bar 5 upon the little lever 2, which, by pulling down the bolt Y, unlocks the drum C from the great wheel B; and then the follower being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs slip over the staple R, and the weight of their heads causes them to fall outward, and shut upon it. Then the weight 4 pushes up the belt Y into the drum, which locks it to the great wheel, and so the ram is drawn up as before.

As the follower comes down, it causes the drum to turn backward, and unwinds the rope from it, whilst the horses, great wheel, trundle, and fly, go on with an uninterrupted motion; and as the drum is turning backward, the counterpoise W is drawn up, and its rope T wound upon the spiral fusy D.

There are several holes in the under side of the drum, and the bolt Y always takes the first one that it finds when the drum stops by the falling of the follower upon the ram; until which stoppage the bolt has not time to slip into any of the holes.

This engine was placed upon a barge on the water, and so was easily conveyed to any place desired. The ram was a ton weight; and the guides *bb*, by which it was let fall, were 30 feet high.

A new machine for driving piles has been invented lately by Mr S. Bunce of Kirby street, Hatten street, London. It will drive a greater number of piles in a given time than any other; and can be constructed more simply to work by horses than Mr Vauloué's engine above described.

Plate
cccxciii.

Fig. 1 and 2 represent a side and front section of the machine. The chief parts are A, fig. 1, which are two endless ropes, or chains connected by cross pieces of iron B (see fig. 2) corresponding with two cross grooves cut diametrically opposite in the wheel C (fig. 1.), into which they are received; and by which means the rope or chain A is carried round. FHK is a side-view of a strong wooden frame moveable on the axis H. D is a wheel, over which the chain passes and turns within at the top of the frame. It moves occasionally from F to G upon the centre H, and is kept in the position F by the weight I fixed to the end K. Fig. 3. L is the iron ram, which is connected with the cross pieces by the hook M. N is a cylindrical piece of wood suspended at the hook at O, which by sliding freely upon the bar that connects the hook to the ram, always brings the hook upright upon the chain when at the bottom of the machine, in the position of GP. See fig. 1.

When the man at S turns the usual crane-work, the ram being connected to the chain, and passing between the guides, is drawn up in a perpendicular direction; and when it is near the top of the machine, the projecting bar Q of the hook strikes against a cross piece of wood at R (fig. 1.); and consequently discharges the ram, whilst the weight I of the moveable frame instantly draws the upper wheel into the position shown at F, and keeps the chain free of the ram in its descent. The hook, while descending, is prevented from catching

the chain by the wooden piece N. For that piece being specifically lighter than the iron weight below, and moving with a less degree of velocity cannot come in contact with the iron till it is at the bottom and the ram stops. It then falls and again connects the hook with the chain, which draws up the ram, as before.

Mr Bunce has made a model of this machine, which performs perfectly well; and he observes, that, as the motion of the wheel C is uninterrupted, there appears to be the least possible time lost in the operation.

Pile-Worms, are a kind of worms found in the piles of the sea-dikes in Holland. They are of very various sizes; for some of the young ones are not above an inch or two in length, while others have been found thirteen or fourteen inches long. The heads of these creatures are covered with two hard shells or hemispheres; which together form a figure resembling an angle; and with which they bore the wood. The best remedy against them is, to perforate the pile with many small holes about an inch asunder: then it must be done over with a varnish in the hottest sun; and, while the varnish is hot, brick-dust must be strewed over it: and this being several times repeated, the pile will be covered with a strong crust absolutely impenetrable to all insects.

FILES, in medicine, the same with hemorrhoids. See MEDICINE, n^o 240, &c.

PILEUS, in Roman antiquity, was the ordinary cap or hat worn at public shows and sacrifices, and by the freedmen. It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining freedom.

PILEWORT (*Ranunculus ficaria*, Lin.), the root. This is a very small plant, found in moist meadows and by hedge sides. The roots consist of slender fibres with some little tubercles among them, which are supposed to resemble the hemorrhoids. From thence it has been concluded, that this root must needs be of wonderful efficacy for the cure of that distemper: to the taste, it is little other than mucilaginous; and although still retained in several of the foreign pharmacopœias, it is hardly in use in this country.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relics of dead saints. See PILGRIMAGE.

The word is formed from the Flemish *pelgrim*, or Italian *pelegrino*, which signifies the same; and those originally from the Latin *peregrinus*, a "stranger or traveller."

PILGRIMAGE, a kind of religious discipline, which consists in taking a journey to some holy place in order to adore the relics of some deceased saint. Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the 11th century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella (A), and Tours; but the greatest numbers now resort to Loretto, in order to visit the chamber of the

5 B 2

bleffed

(A) It deserves to be remarked here, that in the year 1428, under the reign of Henry VI. abundance of licences

Pilgrimage.

bleſſed virgin, in which ſhe was born, and brought up her ſon Jeſus till he was 12 years of age. For the pilgrimage of the followers of Mahomet, ſee MAHOMETANISM, p. 465.

In every country where popery was eſtabliſhed, pilgrimages were common; and in thoſe countries which are ſtill popiſh, they continue. In England, the ſhrine of St Thomas à Becket was the chief reſort of the pious; and in Scotland, St Andrew's; where, as tradition informs us, was depoſited a leg of the holy apoſtle. In Ireland they ſtill continue; for, from the beginning of May till the middle of Auguſt every year, crowds of popiſh penitents from all parts of that country reſort to an iſland near the centre of *Lough-fin*, or *White-Lake*, in the county of Donnegal, to the amount of 3000 or 4000. Theſe are moſtly of the poorer fort, and many of them are proxies for thoſe who are richer; ſome of which, however, together with ſome of the prieſts and biſhops on occaſion, make their appearance there. When the pilgrim comes within ſight of the holy lake, he muſt uncover his hands and feet, and thus walk to the water-ſide, and is taken to the iſland for ſixpence. Here there are two chapels, and 15 other houſes; to which are added confeſſionals, ſo contrived, that the prieſt cannot ſee the perſon confeſſing. The penance varies according to the circumſtances of the penitent; during the continuance of which (which is ſometimes three, ſix, or nine days) he ſubſiſts on oatmeal, ſometimes made into bread. He tra-verſes ſharp ſtones on his bare knees or feet, and goes through a variety of other forms, paying ſixpence at every different confeſſion. When all is over, the prieſt bores a gimblet-hole through the pilgrim's ſtaff near the top, in which he ſiftens a croſs peg; gives him as many holy pebbles out of the lake as he cares to carry away, for amulets to be preſented to his friends, and ſo diſmiſſes him, an object of veneration to all other popiſh not thus initiated; who no ſooner ſee the pilgrim's croſs in his hands, than they kneel down to get his bleſſing.

There are, however, other parts of Ireland ſacred to extraordinary worſhip and pilgrimage; and the number of holy wells, and miraculous cures, &c. produced by them is very great. That ſuch things ſhould exiſt in this enlightened age, and in a Proteſtant country, is indeed ſtrange; but our wonder ceases, when we reflect that it is among the loweſt, and perhaps the worſt of the people. They who carry external religion to an extreme, and place that confidence in ceremony which belongs only to the ſpirit of it, are ſeldom diſtinguiſhed either for their wiſdom or their virtue. We do not deny, however, that they who carry matters to the other extreme, may be equally deſtitute of real knowledge and genuine morality.

Dr Johnson, in his *Raſſelus*, gives us ſome obſervations on pilgrimage, which are ſo much to the purpoſe,

that we think we cannot do better than lay them before our readers. "Pilgrimage (ſaid Imlac, into whoſe mouth the obſervations are put), like many other acts of piety, may be reaſonable or ſuperſtitious according to the principles upon which it is performed. Long journeys in ſearch of truth are not commanded. Truth, ſuch as is neceſſary to the regulation of life, is always found where it is honeſtly ſought: change of place is no natural cauſe of the increaſe of piety, for it inevitably produces diſſipation of mind. Yet ſince men go every day to view the fields where great actions have been performed, and return with ſtronger impreſſions of the event, curioſity of the ſame kind may naturally diſpoſe us to view that country whence our religion had its beginning: and I believe no man ſurveyſes thoſe awful ſcenes without ſome confirmation of holy reſolutions. That the Supreme Being may be more eaſily propitiated in one place than in another, is the dream of idle ſuperſtition; but that ſome places may operate upon our own minds in an uncommon manner, is an opinion which hourly experience will juſtify. He who ſuppoſes that his vices may be more ſucceſſfully combated in Paleſtine, will, perhaps, find himſelf miſtaken; yet he may go thither without folly: he who thinks they will be more freely pardoned, diſhonours at once his reaſon and religion."

PILKINGTON (*Lætitia*), a famous poetical genius, the daughter of Dr Van Lewin, a phyſician of Dublin, where ſhe was born in 1712. She was married very young to the Rev. Matthew Pilkington, a poet alſo of no inconfiderable merit; and theſe two wits, as is often the caſe, lived very unhappily together. They were at length totally ſeparated, on the huſband accidentally diſcovering a gentleman in her bedchamber at two o'clock in the morning; a circumſtance which ſhe accounted for in a very unſatisfactory manner. The ſtory is told at large in her Memoirs; where ſhe ſays, "Lovers of learning, I am ſure, will pardon me, as I ſolemnly declare it was the attractive charms of a new book, which the gentleman would not lend me, but conſented to ſtay till I read it through, that was the ſole motive of my detaining him." As there are not wanting ſome who form objections to marrying learned wives, the chance of ſuch literary aſſignations may perhaps be added to the liſt of them. After this unlucky adventure, Mrs Pilkington came to London; and having recourſe to her pen for ſubſiſtence, through the means of Colley Cibber, ſhe lived ſome time on the contributions of the great. She was however thrown into the Marſhlea for debt; and being ſet at liberty, opened a pamphlet ſhop. She raiſed at length a handſome ſubſcription for her Memoirs; which are written with great ſprightlineſs and wit, containing ſeveral entertaining anecdotes of dean Swift, with whom ſhe was intimate, as well as many pretty little

Pilgrimage, Pilkington.

rences were granted from the crown of England to captains of Engliſh ſhips, for carrying numbers of devout perſons to the ſhrine of St James of Compoſtella in Spain; provided, however, that thoſe pilgrims ſhould firſt take an oath not to take any thing prejudicial to England, nor to reveal any of its ſecrets, nor to carry out with them any more gold or ſilver than what would be ſufficient for their reaſonable expences. In this year there went out thither from England, on the ſaid pilgrimage, the following number of perſons. From London 280, Briſtol 200, Weymouth 122, Dartmouth 90, Yarmouth 60, Jerſey 60, Plymouth 40, Exeter 30, Poole 24, Ipſwich 20, in all 926 perſons.

Pill
||
Pillars.

little pieces of her poetry. This ingenious but unhappy woman is said at last to have killed herself with drinking at Dublin, in 1750.

PILL, in pharmacy, a form of medicine resembling a little ball, to be swallowed whole; invented for such as cannot take bitter and ill-tasted medicinal draughts; as also to keep in readiness for occasional use without decaying. See PHARMACY-Index.

PILLAR, in architecture. See ARCHITECTURE.

PILLAR, in the manege, is the centre of the ring, or manege-ground, round which a horse turns, whether there be a pillar in it or not. Besides this, there are pillars on the circumference or sides of the manege-ground, placed at certain distances, by two and two, from whence they are called the *two pillars*, to distinguish them from that of the centre. The use of the pillar in the centre is for regulating the extent of ground, that the manege upon the volts may be performed with method and justness, and that they may work in a square, by rule and measure, upon the four lines of the volts; and also to break unruly high-mettled horses, without endangering the rider. The two pillars are placed at the distance of two or three paces one from the other; and the horse is put between those, to teach him to rise before and jerk out behind, and put himself upon raised airs, &c. either by the aids or chastisements.

Pompey's PILLAR. See ALEXANDRIA, p. 393.

PILLARS, in antiquarian topography, are large single stones set up perpendicularly. Those of them which are found in Britain have been the work of the Druids; but as they are the most simple of all monuments, they are unquestionably more ancient than druidism itself. They were placed as memorials recording different events; such as remarkable instances of God's mercies, contracts, singular victories, boundaries, and sometimes sepulchres. Various instances of these monuments erected by the patriarchs occur in the Old Testament: such was that raised by Jacob at Luz, afterwards by him named *Bethel*; such also was the pillar placed by him over the grave of Rachel. They were likewise marks of execrations and magical talismans.

These stones, from having long been considered as objects of veneration, at length were by the ignorant and superstitious idolatrously worshipped; wherefore, after the introduction of Christianity, some had crosses cut on them, which was considered as snatching them from the service of the devil. Vulgar superstition of a later date has led the common people to consider them as persons transformed into stone for the punishment of some crime, generally that of sabbath-breaking; but this tale is not confined to single stones, but is told also of whole circles: witness the monuments called the *hurlers* in Cornwall, and *Rollerick stones* in Warwickshire. The first are by the vulgar supposed to have been once men, and thus transformed as a punishment for playing on the Lord's day at a game called *hurling*; the latter, a pagan king and his army.

At Wilton, where the earl of Pembroke has a very magnificent house, there is a pillar of one piece of white Egyptian granite, which was brought from the temple of Venus Genetrix at Rome, near 14 feet high and 22 inches diameter, with an inscription to Astarte or Venus.

PILLORY (*collistrigium*, "collum stringens;" *pilloria*, from the French *pileur*, i. e. *depeculator*, or *plori*; derived from the Greek *πύλη*, *janua*, a "door," because one standing on the pillory puts his head as it were through a door, and *υφω*, *video*), is an engine made of wood to punish offenders, by exposing them to public view, and rendering them infamous. There is a *statute of the pillory*, 51 Hen. III. And by statute it is appointed for bakers, foresters, and those who use false weights, perjury, forgery, &c. 3 *Inft.* 219. Lords of leets are to have a pillory and tumbrel, or it will be the cause of forfeiture of the leet; and a village may be bound by prescription to provide a pillory, &c. 2 *Harwk.* P. C. 73.

PILOT, the officer who superintends the navigation, either upon the sea-coast or on the main ocean. It is, however, more particularly applied by our mariners to the person charged with the direction of a ship; course on or near the sea-coast, and into the roads, bays, rivers, havens, &c. within his respective district.

Pilots of ships, taking upon them to conduct any ship from Dover, &c. to any place up the River Thames, are to be first examined and approved by the master and wardens of the society of Trinity House, &c. or shall forfeit 10 l. for the first offence; 20 l. for the second, and 40 l. for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may pilot his own vessel up the river: and if any ship be lost through the negligence of any pilot, he shall be for ever after disabled to act as a pilot. 3 Geo. I. c. 13. Also the lord-warden of the cinque ports may make rules for the government of pilots, and order a sufficient number to ply at sea to conduct ships up to the Thames: 7 Geo. I. c. 21. No person shall act as a pilot on the Thames, &c. (except in collier ships) without a licence from the master and wardens of Trinity House at Deptford, on pain of forfeiting 20 l. And pilots are to be subject to the government of that corporation; and pay ancient dues, not exceeding 1 s. in the pound, out of wages, for the use of the poor thereof. Stat. 5 Geo. II. c. 20.

By the former laws of France, no person could be received as pilot till he had made several voyages and passed a strict examination; and after that, on his return in long voyages, he was obliged to lodge a copy of his journal in the admiralty; and if a pilot occasioned the loss of a ship, he had to pay 100 livres fine, and to be for ever deprived of the exercise of pilotage; and if he did it designedly, be punished with death. *Lex Mercat.* 70. 71.

The laws of Oleron ordain, That if any pilot designedly misguide a ship, that it may be cast away, he shall be put to a rigorous death, and hung in chains: and if the lord of a place, where a ship be thus lost, abet such villains in order to have a share of the wreck, he shall be apprehended, and all his goods forfeited for the satisfaction of the persons suffering; and his person shall be fastened to a stake in the midst of his own mansion, which, being fired on the four corners, shall be burned to the ground, and he with it. *Leg. Ol.* c. 25. And if the fault of a pilot be so notorious, that the ship's crew see an apparent wreck, they may lead him to the hatches, and strike off his head; but the common law denies this hasty execution: an ignorant pilot

Pillory,
Pilot.

Pilot. pilot is sentenced to pass thrice under the ship's keel by the laws of Denmark. *Lex Mercat.* 70.

The regulations with regard to pilots in the British navy are as follow: "The commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as pilots, and to remove all their objections to his majesty's service, are strictly charged to treat them with good usage, and an equal respect with warrant-officers.

"The purser of the ship is always to have a set of bedding provided on board for the pilots; and the captain is to order the boatswain to supply them with hammocks, and a convenient place to lie in, near their duty, and apart from the common men; when bedding and hammocks are to be returned when the pilots leave the ship.

"A pilot, when conducting one of his majesty's ships in pilot water, shall have the sole charge and command of the ship, and may give orders for steering, setting, trimming, or furling the sails; tacking the ship; or whatever concerns the navigation: and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to observe the conduct of the pilot; and if he judges him to behave so ill as to bring the ship into danger, he may remove him from the command and charge of the ship, and take such methods for her preservation as shall be judged necessary; remarking upon the log-book, the exact hour and time when the pilot was removed from his office, and the reasons assigned for it.

"Captains of the king's ships, employing pilots in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the pilot, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval-officer there, the captain of his majesty's ship shall pay him, and send the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

"Captains of his majesty's ships, employing foreign pilots to carry the ships they command into or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them; whose receipts being duly vouched, and sent, with a certificate of the service performed, to the navy-board, they shall cause them to be paid with the same exactness as they do bills of exchange." *Regulations and Instructions of the Sea-service, &c.*

Pilot-Fish, or *Gasterosteus Ductor*, in ichthyology, is a species of the gasterosteus, and is found in the Mediterranean and in the Atlantic ocean, chiefly towards the equator. Catesby, who gives a figure of it in its natural size, together with a short description, calls it *perca marina sceleris*, or rudder-fish. One of them, which Gronovius describes, was about four inches in length, and its greatest breadth little more than an inch: the head is about the third of the body, and covered, excepting the space between the snout and the eye, with scales scarcely perceptible, and covering one another like tiles; the iris of the eye is a silver grey; the jaws are of equal size, and furnished as well as the palate with small teeth disposed in groups; there is also a longitudinal row of teeth on the tongue. The trunk of the pilot-fish is oblong, a little rounded, but it appears quadrangular towards the tail, because at

this place the lines are thicker, and form a kind of membranaceous projection. The back fin is long, and furnished with seven radii; on the fore-part of this fin are three moveable prickles very short; the fins on the breast have each of them 20 radii, forked at their extremity; the abdominal fins have six; that of the anus has 17 branches, of which the first is longest; this fin is preceded by a small moveable prickle; that of the tail is thick, large, and forked. The pilot-fish is of a brownish colour, changing into gold; a transversal black belt crosses the head; a second passes over the body at the place of the breast; a third near the moveable prickles of the back; three others near the region of the anus; and a seventh at the tail.

Seafaring people observe, that this fish frequently accompanies their vessels; and as they see it generally towards the fore part of the ship, they imagined that it was guiding and tracing out the course of the vessel, and hence it received the name of the *pilot-fish*.

Osbec tells us, that they are shaped like those mackerels which have a transversal line across the body. "Sailors (continues he) give them the name of *pilots*, because they closely follow the dog-fish, swimming in great shoals round it on all sides. It is thought that they point out some prey to the dog-fish; and indeed that fish is very unwieldy. They are not only not touched, but also preserved by it against all their enemies. Psalm cvi. ver. 2. 'Who can utter the mighty acts of the Lord? Who can show forth all his praise?' This scarce and remarkable fish I had an opportunity of describing: it is *Scomber caeruleo-albus cingulis transversis nigris sex, dorso monopterygio*. See the *Memoirs of the Swedish Academy of Sciences for the year 1755*, vol. xvi. p. 71. of the Swedish edition."

It likewise follows the shark, apparently for the purpose of devouring the remains of its prey. It is pretended that it acts as its pilot. The manner in which it attends the shark, according to M. Daubenton, may have given rise to this name. It is said to swim at the height of a foot and a half from the snout of this voracious animal, to follow and imitate all its movements, and to seize with address every part of its prey which the shark allows to escape, and which is light enough to buoy up towards the surface of the water. When the shark, which has its mouth below, turns to seize any fish, the pilot-fish starts away; but as soon as the shark recovers his ordinary situation, it returns to its former place. Barbut informs us, that these fishes propagate their species like the shark. He adds, that in the gulph of Guinea those fishes follow the shark for the sake of the ossials and human excrements; and hence the Dutch give them the name of *dung-fish*. It is remarkable, that though so small they can keep pace with ships in their swiftest course.

PILTEN, a division of Courland, which lies in Courland properly so called, derives its name from the ancient castle or palace of Pilten, built by Valdemar II. king of Denmark about the year 1220, when he founded a bishop's see in this country for the more effectual conversion of its Pagan inhabitants. This district afterwards successively belonged to the Germans, then again to the king of Denmark, the duke of Courland, and to Poland; and by virtue of the instrument of regency drawn up for this district in the year 1717, the government is lodged in seven Polish senators or coun-

Pilot.
Pilten.

Pilum, Pimento. counsellors, from whom an appeal lies to the king. The bishop of Samogitia also styles himself bishop of Pilten.

The most remarkable part of this district is the promontory of Domefnes, which projects northward into the gulf of Livonia. From this cape a sand-bank runs four German miles further into the sea, half of which lies under water, and cannot be discerned. To the east of this promontory is an unfathomable abyss, which is never observed to be agitated. For the safety of vessels bound to Livonia, two square beacons have been erected on the coast, near Domefnes church, opposite to the sand bank, and facing each other. One of these is twelve fathoms high, and the other eight; and a large fire is kept burning on them from the first of August to the first of January. When the mariners see these fires appear as one in a direct line, they may conclude that they are clear of the extremity of the sand bank, and consequently out of danger; but if they see both beacons, they are in danger of running upon it. The district of Pilten contains seven parishes, but no towns worthy of notice. The inhabitants are chiefly of the Lutheran persuasion.

PILUM, a missile weapon used by the Roman soldiers, and in a charge darted upon the enemy. Its point, we are told by Polybius, was so long and small, that after the first discharge it was generally so bent as to be rendered useless. The legionary soldiers made use of the pilum, and each man carried two. The pilum underwent many alterations and improvements, inasmuch that it is impossible with any precision to describe it. Julius Scaliger laboured much to give an accurate account of it, and would have esteemed success on this head amongst the greatest blessings of his life. This weapon appears, however, to have been sometimes round, but most commonly square, to have been two cubits long in the staff, and to have had an iron point of the same length hooked and jagged at the end. Marius made a material improvement in it; for during the Cimbrian war, he so contrived it, that when it stuck in the enemies shield it should bend down in an angle in the part where the wood was connected with the iron, and thus become useless to the person who received it.

PIMENTO, or, as Mr Edward writes, PIEMENTO, in botany, or JAMAICA PEPPER, or *Allspice*, a species of the myrtus. See MYRTUS.

"The pimento trees grow spontaneously, and in great abundance, in many parts of Jamaica, but more particularly on hilly situations near the sea, on the northern side of that island; where they form the most delicious groves that can possibly be imagined; filling the air with fragrance, and giving reality, tho' in a very distant part of the globe, to a great poet's description of those balmy gales which convey to the delighted voyager

‘Sabean odours from the spicy shore

‘Of Araby the blest.

‘Chear'd with the grateful smell, old ocean smiles.’

"This tree is purely a child of nature, and seems to mock all the labours of man in his endeavours to extend or improve its growth: not one attempt in fifty to propagate the young plants, or to raise them from the seeds, in parts of the country where it is not found

growing spontaneously, having succeeded. The usual method of forming a new pimento plantation (in Jamaica it is called a *walk*) is nothing more than to appropriate a piece of woodland, in the neighbourhood of a plantation already existing, or in a country where the scattered trees are found in a native state, the woods of which being fallen, the trees are suffered to remain on the ground till they become rotten and perish. In the course of twelve months after the first season, abundance of young pimento plants will be found growing vigorously in all parts of the land, being without doubt produced from ripe berries scattered there by the birds, while the fallen trees, &c. afford them both shelter and shade. At the end of two years it will be proper to give the land a thorough cleansing, leaving such only of the pimento trees as have a good appearance, which will then soon form such groves as those I have described, and, except perhaps for the first four or five years, require very little attention afterwards.

"Soon after the trees are in blossom, the berries become fit for gathering; the fruit not being suffered to ripen on the tree, as the pulp in that state, being moist and glutinous, is difficult to cure, and when dry becomes black and tasteless. It is impossible, however, to prevent some of the ripe berries from mixing with the rest; but if the proportion of them be great, the price of the commodity is considerably injured.

"It is gathered by the hand; one labourer on the tree, employed in gathering the small branches, will give employment to three below (who are generally women and children) in picking the berries; and an industrious picker will fill a bag of 70lbs. in the day.

"The returns from a pimento walk in a favourable season are prodigious. A single tree has been known to yield 150lbs. of the raw fruit, or one cwt. of the dried spice; there being commonly a loss in weight of one third in curing; but this, like many other of the minor productions, is exceedingly uncertain, and perhaps a very plenteous crop occurs but once in five years."

PIMPINELLA, BURNET SAXIFRAGE; a genus of the digynia order, belonging to the pentandria class of plants. There are seven species; the most remarkable of which are, 1. The major, or greater saxifrage, growing naturally in chalky woods, and on the sides of the banks near hedges, in several parts of England. The lower leaves of this sort are winged; the lobes are deeply sawed on their edges, and sit close to the midrib, of a dark green. The stalks are more than a foot high, dividing into four or five branches. The lower part of the stalk is garnished with winged leaves, shaped like those at the bottom, but smaller: those upon the branches are short and trifid; the branches are terminated by small umbels of white flowers, which are composed of smaller umbels or rays. The flowers have five heart-shaped petals, which turn inward, and are succeeded by two narrow, oblong, channelled seeds. 2. The anisum, or common anise, is an annual plant, which grows naturally in Egypt; but is cultivated in Malta and Spain, from whence the seeds are annually imported into Britain. The lower leaves of this plant are divided into three lobes, which are deeply cut on their edges; the stalk rises a foot and a half high, dividing into several slender branches, garnished with

Pimento, Pimpinella.

Pimpinella
Pin.

narrow leaves, cut into three or four narrow segments, terminated by pretty large loose umbels, composed of smaller umbels or rays, which stand on pretty long footstalks. The flowers are small, and of a yellowish white; the seeds are oblong and swelling.—The former species requires no culture; the latter is too tender to be cultivated for profit in this country. However, the seeds will come up if sown in the beginning of April upon a warm border. When they come up, they should be thinned, and kept clear of weeds, which is all the culture they require.

Uses. Both these species are used in medicine. The roots of pimpinella have a grateful, warm, very pungent taste, which is entirely extracted by rectified spirit: in distillation the menstruum arises, leaving all that it had taken up from the root united into a pungent aromatic resin. This root promises, from its sensible qualities, to be a medicine of considerable utility, though little regarded in common practice: the only officinal composition in which it is an ingredient is the *pulvis ari compostus*. Stahl, Hoffman, and other German physicians, are extremely fond of it; and recommend it as an excellent stomachic, resolvent, detergent, diuretic, diaphoretic, and alexipharmac. They frequently gave it, and not without success, in scorbutic and cutaneous disorders, foulness of the blood and juices, tumors and obstructions of the glands, and diseases proceeding from a deficiency of the fluid secretions in general. Boerhaave directs the use of this medicine in asthmatic and hydropic cases, where the strongest resolvents are indicated: the form he prefers is a watery infusion; but the spirituous tincture possesses the virtues of the root in much greater perfection.

Aniseeds have an aromatic smell, and a pleasant warm taste, accompanied with a degree of sweetness. Water extracts very little of their flavour; rectified spirit the whole.

These seeds are in the number of the four greater hot seeds: their principal use is in cold flatulent disorders, where tenacious phlegm abounds, and in the gripes to which young children are subject. Frederic Hoffman strongly recommends them in weakness of the stomach, diarrhoeas, and for strengthening the tone of the viscera in general; and thinks they well deserve the appellation given them by Helmont, *intestino-um solamen*. The smaller kind of aniseeds brought from Spain are preferred.

PIMPLE, in medicine, a small pustule arising on the face. By mixing equal quantities of the juice of house-leek, *sedum minus*, passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed, which Dr Bughart commends for curing pimples of the face; and says, that the thin liquor separated from it with fugarcandy is an excellent remedy for thick viscid phlegm in the breast.

PIN, in commerce, a little necessary instrument made of brass wire, chiefly used by women in adjusting their dresses.

In the year 1543, by statute 34 and 35 of Henry VIII. cap. vi. it was enacted, "That no person shall put to sale any pinnes but only such as shall be double headed, and have the heads foldered fast to the shank of the pins, well-smoothed, the shank well-sha-

pen, the points well and round filed, cauted, and sharpened." From the above extract it would appear that the art of pin-making was but of late invention, probably introduced from France; and that pin-manufactories since that period have wonderfully improved.

Though pins are apparently simple, their manufacture is, however, not a little curious and complex. We shall therefore give our readers an account of it from Ellis's *Campaigna* of London.

"When the brass-wire, of which the pins are formed, is first received at the manufactory, it is generally too thick for the purpose of being cut into pins. The first operation therefore is that of winding it off from one wheel to another with great velocity, and causing it to pass between the two, through a circle in a piece of iron of smaller diameter: the wire being thus reduced to its proper dimensions, is strained by drawing it between iron pins, fixed in a board in a zig-zig manner, but so as to leave a straight line between them: afterwards it is cut into lengths of three or four yards, and then into smaller ones, every length being sufficient to make six pins; each end of these is ground to a point, which was performed when I viewed the manufactory by boys who sat each with two small grinding stones before him, turned by a wheel. Taking up a handful, he applies the ends to the coarsest of the two stones, being careful at the same time to keep each piece moving round between his fingers, so that the points may not become flat: he then gives them a smoother and sharper point, by applying them to the other stone, and by that means a lad of 12 or 14 years of age is enabled to point about 16,000 pins in an hour. When the wire is thus pointed, a pin is taken off from each end, and this is repeated till it is cut into six pieces. The next operation is that of forming the heads, or, as they term it, *le d spinning*; which is done by means of a spinning-wheel, one piece of wire being thus with astonishing rapidity wound round another, and the interior one being drawn out, leaves a hollow tube between the circumvolutions: it is then cut with sheers; every two circumvolutions or turns of the wire forming one head; these are softened by throwing them into iron pans, and placing them in a furnace till they are red-hot. As soon as they are cold, they are distributed to children, who sit with anvils and hammers before them, which they work with their feet, by means of a lathe, and taking up one of the lengths, they thrust the blunt end into a quantity of the heads which lie before them, and catching one at the extremity, they apply them immediately to the anvil and hammer, and by a motion or two of the foot, the point and the head are fixed together in much less time than it can be described, and with a dexterity only to be acquired by practice; the spectator being in continual apprehension for the safety of their fingers ends. The pin is now finished as to its form, but still it is merely brass; it is therefore thrown into a copper, containing a solution of tin and the leys of wine. Here it remains for some time; and when taken out assumes a white though dull appearance; in order therefore to give it a polish, it is put into a tub containing a quantity of bran, which is set in motion by turning a shaft that runs through its centre, and thus by means of friction it becomes perfectly bright. The
pin

Pin.

Pinacia
|
Pindar.

pin being complete, nothing remains but to separate it from the bran, which is performed by a sieve exactly similar to the winnowing of corn; the bran flying off and leaving the pin behind fit for immediate sale. I was the more pleased with this manufactory, as it appeared to afford employment to a number of children of both sexes, who are thus not only prevented from acquiring the habits of idleness and vice, but are on the contrary initiated in their early years in those of a beneficial and virtuous industry." See NEEDLES.

PINACIA, among the Athenians, were tablets of brass inscribed with the names of all those citizens in each tribe who were duly qualified and willing to be judges of the court of Areopagus. These tablets were cast into a vessel provided for the purpose, and the same number of beans, an hundred being white and all the rest black, were thrown into another. Then the names of the candidates and the beans were drawn out one by one, and they whose names were drawn out together with the white beans were elected judges or senators. In Solon's time there were only four tribes, each of which chose 100 senators; but the number of tribes afterwards increasing, the number of senators or judges increased to so many hundreds more.

PINANG, the Chinese name of the *Arca Catechu*, Lin. See ARECA.

PINCHBECK. See ZINC.

PINDAR, the prince of lyric poets, was born at Thebes, about 520 years B. C. He received his first musical instructions from his father, who was a fluteplayer by profession; after which, according to Suidas, he was placed under Myrtis, a lady of distinguished abilities in lyric poetry. It was during this period that he became acquainted with the poetess Corinna, who was likewise student under Myrtis. Plutarch tells us, that Pindar profited from the lessons which Corinna, more advanced in her studies, gave him at this school. It is very natural to suppose, that the first poetical effusions of a genius so full of fire and imagination as that of Pindar would be wild and luxuriant; and Lucian has preserved six verses, said to have been the exordium of his first essay; in which he crowded almost all the subjects for song which ancient history and mythology then furnished. Upon communicating this attempt to Corinna, she told him smiling, that he should sow with the hand, and not empty his whole sack at once. Pindar, however, soon quitted the leading strings of these ladies, his poetical nurses, and became the disciple of Simonides, now arrived at extreme old age: after which he soon surpassed all his masters, and acquired great reputation over all Greece, but, like a true prophet, he was less honoured in his own country than elsewhere; for at Thebes he was frequently pronounced to be vanquished, in the musical and poetical contests, by candidates of inferior merit.

The custom of having these public trials of skill in all the great cities of Greece was now so prevalent,

VOL. XIV.

Pindar.

that but little fame was to be acquired by a musician or poet any other way than by entering the lists; and we find, that both Myrtis and Corinna publicly disputed the prize with him at Thebes. He obtained a victory over Myrtis, but was vanquished five different times by Corinna. The judges, upon occasions like these, have been frequently accused of partiality or ignorance, not only by the vanquished, but by posterity: and if the merit of Pindar was pronounced inferior to that of Corinna five several times, it was says Pausanias, because the judges were more sensible to the charms of beauty than to those of music and poetry (A). Was it not strange, said the Scythian Anacharsis, that the Grecian artists were never judged by artists, their peers?

Pindar, before he quitted Thebes, had the vexation to see his Dithyrambs traduced, abused, and turned into ridicule, by the comic poets of his time; and Athenæus tells us, that he was severely censured by his brother lyrics, for being a lipogrammatist, and composing an ode from which he had excommunicated the letter S. Whether these censures proceeded from envy or contempt cannot now be determined: but they were certainly useful to Pindar, and it was necessary that he should be lashed for such puerilities. Thebes seems to have been the purgatory of our young bard: when he quitted that city, as his judgement was matured, he avoided most of the errors for which he had been chastised, and suddenly became the wonder and delight of all Greece. Every hero, prince, and potentate, desirous of lasting fame, courted the muse of Pindar.

He seems frequently to have been present at the four great festivals, of the Olympian, Pythian, Nemean, and Isthmian games, as may be inferred from several circumstances and expressions in the odes which he composed for the victors in them all. These at Olympia, who were ambitious of having their achievements celebrated by Pindar, applied to him for an ode, which was first sung in the Prytaneum or town-hall of Olympia, where there was a banqueting room, set apart for the entertainment of the conquerors. Here the ode was rehearsed by a chorus, accompanied by instruments. It was afterwards performed in the same manner at the triumphal entry of the victor into his own country, in processions, or at the sacrifices that were made with great pomp and solemnity on the occasion.

Pindar, in his second Isthmian ode, has apologized for the mercenary custom among poets, of receiving money for their compositions. "The world (says he) is grown interested, and thinks in general with the Spartan philosopher Aristodemus, that *money only makes the man*: a truth which this sage himself experienced, having with his riches lost all his friends." It is supposed that Pindar here alludes to the avarice of Simonides who first allowed his muse to sell her favours to the highest bidder.

5 C

There

(A) Pausanias says, that Corinna was one of the most beautiful women of her time, as he judged by a picture of her which he saw at Tanagris at the place where the public exercises were performed. She was represented with her head ornamented by a ribbon as a memorial of the victories she had obtained over Pindar at Thebes.

Pindar.

There is no great poet in antiquity whose moral character has been less censured than that of Pindar. Plutarch has preserved a single verse of his *Epiccedium* or *Dirge* that was sung at his funeral; which short and simple as it is, implies great praise: *This man was pleasing to strangers, and dear to his fellow-citizens.* His works abound with precepts of the purest morality: and it does not appear that he ever traduced even his enemies; considering himself, for their malignity, by a maxim which he inserted in his first *Pythic*, and which afterwards became proverbial, *That it is better to be envied than pitied.*

Pausanias says, that the character of poet was truly consecrated, in the person of Pindar, by the god of verse himself; who was pleased, by an express oracle, to order the inhabitants of Delphos to set apart for Pindar one half of the first-fruit offerings brought by the religious to his shrine, and to allow him a conspicuous place in his temple, where in an iron chair he used to sit and sing his hymns in honour of that god. This chair was remaining in the time of Pausanias, several centuries after, and shown to him as a relic not unworthy of the sanctity and magnificence of that place.

But though Pindar's muse was pensioned at Delphos, and well paid by princes and potentates else-where, she seems, however, sometimes to have sung the spontaneous strains of pure friendship. Of this kind were, probably, the verses bestowed upon the musician Midas, of Agrigentum in Sicily, who had twice obtained the palm of victory by his performance on the flute at the Pythic games (B). It is in his 12th Pythic ode that Pindar celebrates the victory of Midas over all Greece, upon that instrument which Minerva herself had invented (C).

Fabricius tells us, that Pindar lived to the age of 70; and according to the chronology of Dr Blair, he died 435 years B. C. aged 86. His fellow-citizens erected a monument to him in the Hippodrome at Thebes, which was still subsisting in the time of Pausanias; and his renown was so great after his death, that his posterity derived very considerable honours and privileges from it. When Alexander the Great attacked the city of Thebes, he gave express orders to his soldiers to spare the house and family of Pindar. The Lacedemonians had done the same before this period; for when they ravaged Boeotia and burned the capital, the following words were written upon the door of the poet: *Forbear to burn this house, it was the dwelling of Pindar.* Respect for the memory of this great poet continued so long, that, even in Plutarch's time, the best part of the sacred victim at the Theoxenia festival was appropriated to his descendants.

PINDARIC ode, in poetry, an ode, formed in imitation of the manner of Pindar. See POETRY, n^o 136, &c.

PINDUS (anc. geog.), not a single mountain, but a chain of mountains, inhabited by different people of Epirus and Thessaly; separating Macedonia, Thessaly and Epirus: An extensive chain, having Macedonia to the north, the Peneus to the west, the Dolopes to the south, and the mountain itself of Thessaly (Strabo).

PINDUS, a Doric city of Ætolia, situated on the cognominal river, which falls into the Cephalius (Strabo).

PINE, in botany. See PINUS.

PINE-Apple. See BROMELIA.

PINEA, or PIGNE, in commerce; is a term used in Peru and Chili, for a kind of light, porous masses, or lumps, formed of a mixture of mercury and silver-dust from the mines. The ore, or mineral, of silver, when dug out of the veins of the mine, is first broken and then ground in mills for the purpose, driven by water with iron pestles, each of 200 pounds weight. The mineral, when thus pulverized, is next sifted, and then worked, up with water into a paste; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about two thousand five hundred pounds.

Each piece or *cuerpo* is again kneaded up with sea-salt, which, dissolving, incorporates with it. They then add mercury, from 10 to 20 pounds for each *cuerpo*, kneading the paste afresh until the mercury be incorporated therewith. This office, which is exceedingly dangerous on account of the noxious qualities of the mercury, is always made the lot of the poor Indians. This amalgamation is continued for eight or nine days; and some add lime, lead, or tin ore, &c. to forward it; and in some mines, they are obliged to use fire. To try whether or no the mixture and amalgamation be sufficient, they wash a piece in water; and if the mercury be white, it is a proof that it has had its effect; if black, it must be still farther worked. When finished, it is sent to the lavatories, which are large basons that empty successively into one another. The paste, &c. being laid in the uppermost of these, the earth is then washed from it into the rest by a rivulet turned upon it; an Indian, all the while, stirring it with his feet, and two other Indians doing the like in the other basons. When the water runs quite clear, out of the basons, the mercury and silver are found at bottom incorporated. This matter they call *peña*, and of this they form the pineas, by expressing as much of the mercury as they can; first, by putting it in woollen bags, and pressing and beating it strongly; then, by stamping it in a kind of wooden mould, of an octagonal form, at bottom whereof is a brass plate pierced

Pindaric
||
Pinea.

(B) This Midas is a very different personage from his long-eared majesty of Phrygia, whose decision in favour of Pan had given such offence to Apollo; as is manifest, indeed, from his having been cotemporary with Pindar.

(C) The most extraordinary part of this musician's performance that can be gathered from the scholiast upon Pindar, was his finishing the solo, without a reed or mouth-piece, which broke accidentally while he was playing. The legendary account given by the poet in this ode, of the occasion upon which the flute was invented by Minerva, is diverting: "It was (says he) to imitate the howling of the Gorgons, and the hissing of their snakes, which the goddess had heard when the head of Medusa (one of these three anti-graces), was cut off by Perseus."

Pineal
Gland,
Pineau.

pierced full of little holes. The matter, when taken out of the mould, is laid on a trivet, under which is a large vessel full of water; and the whole being covered with an earthen head, a fire is made around it.

The mercury still remains in the mass and is thus reduced into fumes, and, at length condensing, it is precipitated into the water, leaving behind it a mass of silver grains of different figures, which, only joining or touching at the extremes, render the matter very porous and light. This, therefore, is the pinea, or pigne, which the workmen endeavour to sell secretly to vessels trading to the South sea; and from which those, who have ventured to engage in so dangerous a commerce, have made such vast gains. Indeed the traders herein must be very careful; for the Spanish miners are arrant knaves, and to make the pignes weigh the more, they often fill the middle with sand or iron.

PINEAL GLAND. See ANATOMY.

PINEAU (Severin du), who died at Paris in 1619, was a native of Chantilly, and first surgeon to the king of France. He was very skilful in lithotomy; and has left behind him, 1. A discourse concerning the Extraction of the Stone in the Bladder, published in 1610 in 8vo. 2. A treatise *De Virginitatis Notis*, printed at Leyden 1641, in 12mo. This last performance, however useful it may be to men of science, we would not venture to recommend to the perusal of young people, on account of some particulars which it was perhaps unnecessary to expose to the eyes of the public.

PINEAU (Gabriel du), was born at Angers in 1573, where he followed the profession of a lawyer with a reputation above his years. He went afterwards to Paris, and pled with éclat before the parliament and great council. Upon his return to Angers, he became a counsellor in the presidial court. He was consulted by all the neighbouring provinces, and had an active hand in all the great affairs of his time. Mary de Medicis conferred upon him the office of master of requests, and in her disgrace wished to support herself by his credit and counsels; but Du Pineau, always attentive to what he owed on the one hand to the mother of his king, and on the other to the king himself, never ceased to inspire that princess with sentiments of peace.

In 1632 Louis XIII. by way of reward, appointed him mayor and captain-general of the city of Angers; a situation in which he merited the flattering title of *Father of the People*. He had no respect of persons; for he was equally accessible to the poor and the great. This worthy citizen died the 15th of October 1644, at the age of 71. His house was a kind of academy, where regular conferences were held, and attended by young officers, advocates, and other literary characters. In these conferences every one freely stated the difficulties which occurred to him upon subjects either of law or history; and when Pineau spoke, all was made clear; but he was always the last in delivering his sentiments, because he perceived that too much deference was paid to his opinion. His writings are, 1. Latin notes, in addition to those of Du Moulin, upon the canon law, and printed along with the works of that eminent lawyer by the care of Francis Pinson. 2. Commentaries, observations, and consultations, upon several important questions respecting the laws both of

Anjou and of France, with some dissertations upon different subjects. &c. reprinted in 1725 in 2 vols. fol. by the care of Livoniere, who has enriched them with very useful remarks. The editor says, that "Du Pineau is a little inferior to the celebrated Du Moulin on the civil law, but that he is more accurate than the other upon the canon law."—Ménage made these two verses upon his death.

*Pineilus perit, Themidis pius ille sacerdos,
In proprio iudex limine perpetuus.*

PINEDA (John) who was born at Seville of a noble family, entered into the society of Jesuits in 1572. He taught philosophy and divinity in several colleges; and devoted his time to the study of the Holy Scriptures. That he might render that study the easier, he made himself master of the oriental languages. We have of his writings, 1. Two volumes of Commentaries upon the book of Job, in folio. 2. Two upon Ecclesiastes. 3. A General History of the Church, in Spanish, 4 vols. in folio. 4. A History of Ferdinand III, in the same language, in folio. He died in 1637, much regretted by the members of his society, and by the public in general.

PINELLI (John Vincent), born at Naples, was son of Count Pinelli, a noble Genovese, who had settled in that city, and had acquired a handsome fortune in the way of trade. After receiving a liberal education he quitted the place of his nativity, and repaired to Padua, where he took up his residence at the age of 24. Being a great lover of science, he gave a preference to that city on account of its famous university, which brought to it a number of learned men. He had an excellent library, which consisted of a choice collection of books and manuscripts, and which he continued to enrich till the hour of his death. His literary correspondence, not only in Italy, but through the most of Europe, procured him all the new works which were worthy of a place in his collection. The authors themselves were often forward to pay their respects to him. In many cities of Italy he had persons employed to search, at least once a month, the stalls of those artificers who make use of old parchments, such as lute-makers, sieve-wrights, and others; and by this means he had the good fortune often to save from destruction some valuable fragments. His passion for knowledge embraced all the sciences; but History, medals, antiquities, natural history, and particularly botany, were his favourite studies. He was consulted from all quarters, and the extent of his acquaintance with the learned world was very great. He corresponded with Justice Lipsius, Joseph Scaliger, Sigonius, Possevin, Peter Pitheu, and a great many others, who have all paid the highest compliments to his erudition. Insensible to all the pleasures of life, and acquainted only with those of the mind, he had a great dislike to plays, entertainments, shows, and every thing which most excites the curiosity of other men. During the space of 43 years that he lived at Padua, he was never known to be out of the city but twice; once on occasion of a plague which infested it; and afterwards on a voyage to Naples, which he made at the earnest solicitation of his friends. In short, Pinelli was generous, sympathizing, and compassionate, particularly to men of letters, whose wants he often anticipated. His zeal

Pinelli.

Pinet
||
Pinguicula.

for the progress and advancement of science rendered him very communicative of his knowledge and of his books; but this was always done with judgment and discretion. He died in 1601, aged 63, without having published any work. Paul Gualdo, who has written Pinelli's life, does not specify the number of volumes of which his rich library consisted: he only informs us, that when it was transported by sea to Naples, it was packed up in 130 chests, of which 14 contained manuscripts; but did not go wholly to his heirs. The senate of Venice caused their seal to be set upon the manuscripts, and took away whatever concerned the affairs of the republic, to the number of 200 pieces.—“I compare (says president de Thou) Pinelli to Titus Pomponius; for, as that illustrious Roman was called *Attick*, Pinelli also bore the title of *Venetian*, on account of the great affection which the republic of Venice had for him.

PINET (Antony du), lord of Noroy, lived in the 16th century, and was a native of Besançon. He was strongly attached to the protestant religion, and a bitter enemy to the church of Rome. His book, intitled *La Conformité des Eglises Reformées de France*, and *de l'Eglise primitive*, printed at Lyons, 1564, in 8vo; and the notes which he added to the French translation of the Fees of the Pope's Chancery, which was printed at Lyons, in 8vo, 1564, and reprinted at Amsterdam in 1700, in 12mo, plainly discover his sentiments. He published the last mentioned performance under this title: *Taxe des parties casuelles de la boutique du Pape*, in Latin and French, with some notes taken from Decrees, councils, and canons, in order to ascertain the discipline anciently observed in the church. In the epistle dedicatory, he assumes the tone of a declared enemy to the court of Rome. He apologizes for having presented this book “to a society so holy as yours (the protestants), in which are heard only hymns, psalms, and praises to the Lord our God: but it is proper to show to the villain his villainy, and the fool his folly, lest one should be thought to resemble them.” We see by this specimen, that Pinet had no more politeness in his style than in his manners. His translation of Pliny's Natural History, printed at Lyons, in 2 vol. folio, 1566, and at Paris, 1608, was formerly much read. Though there are a good many errors in it, it is yet very useful at present, especially for those who understand Pliny's Latin, on account of the translator's researches, and a great number of marginal notes. Pinet also published Plans of the principal fortresses in the world, at Lyons, 1564, in folio.

PING-LEANG FOU, a city of China in the Province of Chen-si. It is one of the most considerable cities of the western part of the province, and is situated on the river Kin-ho. The air here is mild; and the agreeable views which the surrounding mountains present, added to the streams which water the country, render it a very delightful residence. It has under its jurisdiction three cities of the second class and seven of the third. In this district a valley so deep and narrow, that it is almost impervious to the light: a large highway, paved with square stones, runs through it.

PINGUICULA, BUTTERWORT: a genus of the monogynia order, belonging to the diandria class of plants. There are four species; of which the most re-

markable is the vulgaris, or common butterwort, *Pinguicula*, growing commonly on bogs or low moist grounds in England and Scotland. Its leaves are covered with soft, upright pellucid prickles, secreting a glutinous liquor. The flowers are pale red, purple, or deep violet colour, and hairy within. If the fresh gathered leaves of this plant are put into the strainer through which warm milk from the cow is poured, and the milk set by for a day or two to become accefcnt, it acquires a consistency and tenacity, and neither whey nor cream separate from it. In this state it is an extremely grateful food, and as such is used by the inhabitants of the north of Sweden. There is no further occasion to have recourse to the leaves; for half a spoonful of this prepared milk, mixed with fresh warm milk, will convert it to its own nature, and this again will change another quantity of fresh milk, and so on without end. The juice of the leaves kills lice; and the common people use it to cure the cracks or chops in cows udders. The plant is generally supposed injurious to sheep, by occasioning in them that disease called the *rot*. But from experiments made on purpose, and conducted with accuracy, it appears, that neither sheep, cows, goats, horses, or swine will feed upon this plant.

Wherever this plant, called also *Yorkshire sanicle*, is found, it is a certain indication of a boggy soil. From the idea that the country people have of its noxious operation on sheep, this plant has been called the *white rot*; since as they imagine it gives them the rot whenever they eat it, which they will not do but from great necessity.

The Laplanders, like the Swedes with the milk of cows, receive that of the rein-deer upon the fresh leaves of this plant, which they immediately strain off and set aside till it becomes somewhat accefcnt; and the whole acquires in a day or two the consistence of cream without separating the serum, and thus becomes an agreeable food. When thus prepared a small quantity of the same has the property of rennet in producing the like change on fresh milk.

PINGUIN, or PENGUIN, in ornithology, a genus of birds of the order of palmipedes; distinguished by Mr Latham by the following characters. The bill is strong, straight, more or less bending towards the point, and furrowed on the side; the nostrils are linear, and placed in the furrows; the tongue is covered with strong spines, pointing backwards; the wings are small, very like fins, and covered with no longer feathers than the rest of the body, and are useless in flight; the body is clothed with thick short feathers, having broad shafts, and placed as compactly as the scales of fishes; the legs are short, thick, and placed very near the vent; the toes are four, and are all placed forwards, the interior are loose, and the rest are webbed; the tail is very stiff, consisting of broad shafts scarcely webbed.

It is agreed that Pinguins are inhabitants of southern latitudes only; being, as far as is yet known, found only on the coasts of South America from Port Desire to the Straits of Magellan; and Frezier says they are found on the western shore as high as Conception. In Africa they seem to be unknown, except on a small isle near the Cape of Good Hope, which takes its name from them. They are found in vast numbers on land during the breeding season; for they seldom come on shore but at that time: they form burrows under ground

P. 92.

Pinguin. ground like rabbits; and the isles they frequent are perfectly undermined by them.

Their attitude on land is quite erect, and on that account they have been compared by some to pygmies, by others to children with white bibs. They are very tame, and may be driven like a flock of sheep. In water they are remarkably active, and swim with vast strength, assisted by their wings, which serve instead of fins. Their food in general is fish; not but that they will eat grass-like geese.

Mr Latham remarks, that this genus appears to hold the same place in the southern division of the earth that the awks do in the northern; and that, however authors may differ in opinion on this head, they ought not to be confounded with one another. The pinguin is never seen but in the temperate and frigid zones south of the equator, while the awk only appears on the parallel latitudes north of the equator; for neither of these genera have yet been observed within the tropics. Forster, in his voyage (vol. i. page 92.), says, he saw one for the first time in lat. 48. south, nor are they ever met with nearer than 40 degrees south. *Id. Introd. Disc. on Pinguins, Comment. Göt. vol. 3d.*

The wings of the pinguin are scarcely any thing else than mere fins, while the awk has real wings and gills, though they be but small. The former has four toes on each foot, the latter only three. While swimming, the pinguin sinks wholly above the breast, the head and neck only appearing out of the water; while the awk, like most other birds, swims on the surface. There are several other peculiarities which serve to distinguish the two genera, but what we have mentioned are doubtless sufficient.

“The bodies of the pinguin tribe (says our author) are commonly so well and closely covered with feathers that no wet can penetrate; and as they are in general excessively fat, these circumstances united secure them from cold. They have often been found above 700 leagues from land; and frequently on the mountains of ice, on which they seem to ascend without difficulty, as the soles of their feet are very rough and suited to the purpose.” Mr Latham enumerates nine different species of this genus, besides two varieties of the black-footed pinguin or diomedea.

1. The first, which is a very beautiful species, our author calls the *crested* pinguin. The birds of this species are 23 inches long; the bill is three inches long, and of a red colour, with a dark furrow running along on each side to the tip; the upper mandible is curved at the end, the under is obtuse; the irides are of a dull red; the head, neck, back, and sides are black. Over each eye there is a stripe of pale yellow feathers, which lengthens into a crest behind, nearly four inches long; the feathers on each side of the head, above this stripe, are longer than the rest, and stand upward, while those of the crest are decumbent but can be erected on each side at pleasure; the wings, or rather fins, are black on the outside, edged with white; on the inside they are white; the breast and all the under parts are also white; the legs are orange, and the claws are dusky. The female has a streak of pale yellow over the eye, but it is not prolonged into a crest behind as in the male.

This species inhabits Falkland's Islands, and was likewise met with in Kerguelen's Land, or the of Diomedea

lation, as well as at Van Diemen's Land, and New Holland, particularly in Adventure Bay. They are called *hopping pinguins* and *jumping jacks*, from their action of leaping quite out of the water, on meeting with the least obstacle, for three or four feet at least; and indeed, without any seeming cause they often do the same, appearing chiefly to advance by that means. This species seems to have a greater air of liveliness in its countenance than others, yet is in fact a very stupid bird, so much so as to suffer itself to be knocked on the head with a stick when on land. Forster says he found them difficult to kill, and when provoked, he adds, they ran at the sailors in flocks, and pecked their legs, and spoiled their clothes. When angered too they erect their crests in a beautiful manner. These birds make their nests among those of the pelican tribe, living in tolerable harmony with them; and lay seldom more than one egg, which is white, and larger than that of a duck. They are mostly seen by themselves, seldom mixing with other pinguin, and often met with in great numbers on the outer shores, where they have been bred. They are frequently so regardless as to suffer themselves to be taken by the hand. The females of this species lay their eggs in burrows, which they easily form of themselves with their bills, throwing out the dirt with their feet. In these holes the eggs are deposited on the bare earth. The general time of sitting is in October; but some of the species, especially in the colder parts, do not sit till December, or even January. How long they sit is not known.

2. The second species mentioned by Latham is the *patagonian*. It is distinguished by this name not only because it is found on that coast, but also because it exceeds in bulk the common pinguins as much as the natives are said to do the common race of men. It was first discovered by Captain Macbride, who brought one of them from Falkland Islands off the Straits of Magellan. The length of the stuffed skin of this particular bird measured four feet three inches, and the bulk of the body seemed to exceed that of a swan. The bill was four inches and a half long, slender, straight bending on the end of the upper mandible, with no nostrils. The tongue half the length of the bill, and singularly armed with strong sharp spines pointing backwards. The plumage is most remarkable, the feathers lying over one another with the compactness of the scales of a fish; their texture equally extraordinary; the shafts broad and very thin; the vanes unwebbed; the head, throat, and hind part of the neck, are of a deep brown colour; from each side of the head to the middle of the fore part of the neck are two lines of bright yellow, broad above, narrow beneath, and uniting half way down; from thence the same colour widens towards the breast fading away till it is lost in pure white, of which colour is the whole under side of the body, a dusky line dividing it from the colour of the upper part. The whole back is of a very deep ash-colour almost dusky; but the end of each feather is marked with a blue spot, those about the junction of the wings larger and paler than the others. The wings are in this species, as in all the others, extremely short in respect to the size of the bird; hang down and have the appearance of fins, whose office they perform; their length is only 14 inches; on the outside they are dusky, and covered

Pinguin.

Plate
cccxcvii.Latham's
Synopsis.

covered

Pinguin. were I with scale-like feathers, or at best, with such whose shafts are so broad and flat as scarce to be distinguished from scales; those on the ridge of the wings consisting entirely of shaft; the larger, or quill feathers, have some very short webs. The tail consists of 30 brown feathers, or rather thin shafts, resembling split whale-bone; flat on the upper side, concave on the under, and the webs short unconnected, and brittle. From the knees to the end of the claws six inches, covered with strong peritargular black scales; the fore toe scarce an inch long, and the others so remarkably short, as to evince the necessity of that strength of the tail, which seems intended as a support to the bird in its erect attitude; in the same manner as that of the woodpecker is when it clings to the sides of trees: between the toes is a strong femilunar membrane, continued up even part of the claws; the middle claw is near an inch long, and the inner edge very sharp and thin; the interior toe is small, and placed very high. The skin is extremely tough and thick; which, with the closeness of the feathers, guards it effectually in the element wherein it is so conversant.

This species, which was, as we have seen, first met with in Falkland Islands has since been seen in Kerguelen's Land, New Georgia, and New Guinea. M. Bougainville caught one, which soon became so tame as to follow and know the person who had care of it: it fed on flesh fish, and bread; but after a time grew lean, pined away, and died. The chief food, when at large, is thought to be fish; the remains of which, as well as crabs, shell-fish, and molusca were found in the stomach this species is the fattest of the tribe; and therefore molt so in January when they moult. They are supposed to lay and sit in October. They are met with in the most deserted places. Their flesh is black, though not very unpalatable. This has been considered as a solitary species, but has now and then been met with in considerable flocks. They are found in the same places as the papuan pinguins, and not unfrequently mixed with them; but in general show a disposition of associating with their own species.

3. The third species is denominated *papuan*. It is about 2½ feet long being a little bigger than that which is called the *Case pinguin*. This species inhabits the Isle of Papos, or New Guinea; and has been met with at Falkland Isles and Kerguelen's Land; it is often found among the patagonian pinguins.

4. The antarctic pinguin is about 25 inches long, and weighs about 11½ pounds. The bill is upwards of 2½ inches long; the upper parts of the body are black, the under are glossy white; beneath the chin there is a narrow streak of a blackish colour, passing backward towards the hind head, a little bent about the region of the ears; the wings are much the same as in the other species; the tail is cuneiform; the feathers, or rather bristles, of which it is composed are black and in number 32; the legs are of a flesh colour, and the soles of the feet are black.

"This species (says Latham) inhabits the south sea, from 38 degrees to the antarctic circle; and is frequently found on the ice mountains and islands, on which it ascends; it is a pretty numerous species. Our last voyagers found them in plenty on the Isle of Desolation. And it was observed, that in an island they touched at, not greatly distant, the rocks were almost

covered with pinguins and shags; the first most probably of this sort.

5. For the black-footed pinguin, or diomedea demersa, see DIOMEDEA.

6. The magellanic species is about the size of the antarctic pinguin. They are about 2 feet and sometimes 2½ feet long, and weigh 11 pounds. The bill is black, having a transverse band across near its tip; the head and neck are black, except a few markings here and there; the upper parts of the body and wings are of the same colour; the under parts of both are white from the breast, except a narrow band of black passing at a little distance within the white on the breast, and downwards on each side, beneath the wings quite to the thighs; the legs are of a reddish colour, irregularly spotted on the thighs; and the claws are black. This species, which is very numerous inhabits the Straits of Magellan, Staten Land, Terra del Fuego, and Falkland islands. Far from being timid, these birds will often attack a man and peck his legs. As food they are not at all unpalatable. They often mix with sea-wolves among the rushes, burrowing in holes like a fox. They swim with prodigious swiftness. They lay their eggs in collective bodies, resorting, in incredible numbers to certain spots, which their long residence has freed from grass, and to which were given the name of towns.—Penrose observes, that they composed their nests of mud, a foot in height, and placed as near one another as may be. It is possible that they may have different ways of nesting, according to the places they inhabit; or perhaps the manners of this may be blended with those of another. "Here, (says he, &c. in the places they frequent), during the breeding season, we were presented with a sight which conveyed a most dreary, and I may say awful idea of the desertion of these islands by the human species:—a general stillness prevailed in these towns; and whenever we took our walks among them in order to provide ourselves with eggs, we were regarded indeed with side-long glances, but we carried no terror with us.

"The eggs are rather larger than those of a goose, and laid in pairs. When we took them once, and sometimes twice in a season, they were as often replaced by the bird; but prudence would not permit us to plunder too far, lest a future supply in the next year's brood might be prevented." They lay some time in November driving away the albatrosses, which have hatched their young in turn before them. The eggs were thought palatable food, and were preserved good for three or four months.

7. The collared pinguin is a very little less than the papuan, being 18 inches long. The bill, which is black, is similar to that of the patagonian pinguin; the sides are black; the eye is surrounded with a bare skin of a blood colour, of an oval shape, and three times as large as the eye itself; the head, throat, hind part of the neck, and sides, back, wings, and tail, are all black; the fore part of the neck, breast, belly, and thighs, are white extending round the neck, where the white begins like a collar, except that it does not quite meet at the back part; the legs are black.

This species inhabits New Guinea. It was also seen by Dr Forster near Kerguelen's Land; and again on two isles adjoining to the island of South Georgia.

Pinguin.

Pinion
||
Pinna.

1. For the red-footed penguin, or phaeton demersus, see PHAETON.

9. The *small*, or, as Latham calls it, the *little penguin*, is about the size of a teal, being 15 inches long. The bill, which is of a dusky colour, is about $1\frac{1}{2}$ long, and shaped like that of the phaeton demersus: the upper parts of the bird from the head to the tail appear to be of a cinereous blue colour, of which colour are the ends of the feathers; the base of them, however, is brown black, and the shafts of each of the same colour; the under parts from chin to vent are white; the wings are dusky above and white beneath; the tail, which is exceedingly short, consists of 16 stiff feathers, which are scarcely perceptible; the legs are of a dull red colour; the webs are dusky, and the claws are black.

This species is pretty commonly found among the rocks on the southern parts of New Zealand, but they are most frequent at Dusky Bay. They make deep burrows on the sides of the hills, in which they lay their eggs: these holes are so thick in some parts, that a person is scarcely able to walk three or four steps without falling into one of them up to the knees. The inhabitants of Queen Charlotte's Sound kill them with sticks, and, after skinning them, esteem the flesh as good food. They are known at New Zealand by the name of *Korora*.—"These birds (says Latham), I have found to vary both in size and colour: some are much smaller than others, quite black above, and measure only 13 inches in length; others are rather larger, and of a plain lead-colour on the upper parts, and the wings black, though all are white, or nearly so, beneath. The legs in these two last are marked with black at the ends of the toes; and the claws are black."

PINION, in mechanics, an arbor, or spindle, in the body whereof are several notches, which catch the teeth of a wheel that serves to turn it round, or it is a lesser wheel that plays in the teeth of a larger.

PINK, a name given to a ship with a very narrow stern; whence all vessels, however small, whose sterns are fashioned in this manner, are called *pink stern'd*.

PINK, in botany. See DIANTHUS.

Plate
CCCXCI. PINNA, in zoology; a genus belonging to the order of vermes testacea. See MYTILUS, n° 6. The animal is a slug. The shell is bivalve, fragile, and furnished with a beard; gapes at one end; the valves hinge without a tooth. They inhabit the coasts of Provence, Italy, and the Indian ocean. The largest and most remarkable species inhabits the Mediterranean. It is blind, as are all of the genus; but furnished with very strong calcareous valves. The scuttle-fish (*Scopia*), an inhabitant of the same sea, is a deadly foe to this animal: as soon as the pinna opens its shell, he rushes upon her like a lion; and would always devour her, but for another animal whom she protects within her shell, and from whom in return she receives very important services. It is an animal of the crab kind (see CANCER, n° 15.), naked like the hermit and very quick-sighted. This cancer or crab the pinna receives into her covering; and when she opens her valves in quest of food, lets him out to look for prey. During this the scuttle fish approaches; the crab returns with the utmost speed and anxiety to his hostess, who being thus warned of the danger shuts her doors, and keeps out the enemy. That very sagacious

Pinna.

observer Dr Hæffelquist, in his voyage towards Palestine, beheld this curious phenomenon, which tho' well known to the ancients had escaped the moderns. Aristotle (*Hist. lib. 5. c. 15.*) relates, that the pinna kept a guard to watch for her: That there grew to the mouth of the pinna a small animal, having claws, and serving as a caterer, which was like a crab, and was called the *pinna-phylax*. Pliny (*lib. 9. 31.*) says, the smallest of all the kinds is called the *pinnaeres*, and therefore liable to injury; this has the prudence to hide itself in the shells of oysters. Again, *lib. 9. 65.* he says, the pinna is of the genus of shell-fish; it is produced in muddy waters, always erect, nor ever without a companion, which some call the *pinnaeres*, others the *pinna-phylax*. This sometimes is a small squill, sometimes a crab, that follows the pinna for the sake of food. The pinna upon opening its shell, exposes itself as a prey to the smallest kind of fishes; for they immediately assault her, and, growing bolder upon finding no resistance, venture in. The guard watching its time gives notice by a bite; upon which the pinna, closing its shell, shuts in, kills, and gives part of what ever happens to be there to its companion.

The pinna and the crab together dwell,
For mutual succour, in one common shell.
They both to gain a livelihood combine;
That takes the prey, when this has given the sign.
From hence this crab, above his fellows fam'd,
By ancient Greeks was *pinnaeres* nam'd.---OPPIAN.

The pinna marina differ less from muscles in the size of the shells than in the fineness and number of certain brown threads which attach them to the rocks, hold them in a fixed situation, secure them from the rolling of the waves, especially in tempests, and assist them in laying hold of slime. See MYTILUS, p. 611. note (v). These threads, says Rondelet, are as fine, compared with those of muscles, as the finest flax is compared with tow. M. de Reaumur says, that these threads are nearly as fine and beautiful as silk from the silk-worm, and hence he calls them the *silk-worms of the sea*. Stuffs, and several kinds of beautiful manufacture, are made of these threads at Palermo; in many places they are the chief object of fishing, and become a silk proper for many purposes. It requires a considerable number of the pinna marina for one pair of stockings. Nothing can equal the delicacy of this singular thread. It is so fine, that a pair of stockings made of it can be easily contained in a snuff-box of an ordinary size. In 1754, a pair of gloves or stockings of these materials was presented to Pope Benedict XIV. which, notwithstanding their extreme fineness, secured the leg both from cold and heat. A robe of the same singular materials was the gift of the Roman emperor to the Satraps of Armenia. See *Preceptus de Elif.* lib. 3. c. 1. A great many manufacturers are employed in manufacturing these threads into various stuffs at Palermo and other places.

The men who are employed in fishing up the pinna marina, inform us, that it is necessary to break the tuft of threads. They are fished up at Toulon, from the depth of 15, 20, and sometimes more than 50, feet, with an instrument called a cramp. This is a kind of fork of iron, of which the prongs are perpendicular with respect to the handle. Each of them is

Pinna
||
Pint.

about eight feet in length, and there is a space between them of about six inches; the length of the handle is in proportion to the depth of the water; the pinnae are seized, separated from the rock, and raised to the surface by means of this instrument. The tuft of silk issues directly from the body of the animal; it comes from the shell at the place where it opens, about four or five inches from the summit or point in the large pinna.

M. de Reaumur, *Mém. de l'Acad. des Sciences*, 1711, page 216, and 1717, page 177, considers the pinna as the most proper of all shell-fish to elucidate the formation of pearls. It produces many of them of different colours, as grey or lead-coloured, red, and some of a blackish colour, and in the form of a pear.

M. d'Argenville distinguishes three kinds of the pinna: 1st, The large kind, which are red within, and which have reddish mother-of-pearl, similar to the substance of the shell itself. There are of those shells which weigh near 15 pounds. This is the *ostrea* of the Venetians.

2^d, The smaller kind. Some of these are slender, *pyrreus*, of the colour of horn, a little shaded with pale red.

3^d, The kind called *perna*. These are adorned with points in the channels of their shell; but what is very singular, the edges of the shell are thicker at the openings than at the joining of the valves.

The animal which lodges in the pinna marina rarely shows itself because the valves are seldom opened. Its head is below, its largest extremity opposite; it is kept in the shell by four vigorous muscles, placed at the extremities of the valves; the shell has no hinges, but a flat and blackish ligament, which is equal in length to one-half of the shell. See PINNOTERUS and PEARL.

PINNACE, a small vessel navigated with oars and sails, and having generally two masts, which are rigged like those of a schooner.

PINNACE is also a boat usually rowed with eight oars. See the article BOAT.

PINNACLE, in architecture, the top or roof of an house, terminating in a point. This kind of roof among the ancients was appropriated to temples; their ordinary roofs were all flat, or made in the platform way.

PINNATED LEAVES, in botany. See BOTANY, p. 445. n^o 232.

PINNATIFID, do. p. 442. n^o 103.

PINNOTERUS, or PINNOPHYLAX, is a kind of crab-fish, furnished with very good eyes. It is said to be the companion of the pinna marina. They live and lodge together in the same shell, which belongs to the latter. When it has occasion to eat, it opens its valves, and sends out its faithful purveyor to procure food. If during their labour the pinnoterus perceives the polypus, it immediately returns to warn its blind friend of the danger, when, by shutting its valves, it escapes the rage of its enemy; but when the pinnoterus loads itself with booty without molestation, it makes a gentle noise at the opening of the shell, and when admitted the two friends feast on the fruits of its industry. See PINNA, &c.

PINT (*pinta*), a vessel, or measure, used in estimating the quantity of liquids, and even sometimes of

dry things.—Badius derives the word from the Greek *πινθος*; others from the German *pint*, a little measure of wine; Nicod from the Greek *πινος*, "to drink."

The *English pint* is twofold; the one for wine measure, the other for beer and ale-measure. See MEASURE.

PINTADA, a species of PROCELLARIA.

PINTLES, certain pints or hooks fastened upon the back part of the rudder, with their points downwards, in order to enter into, and rest upon, the *gongings*, fixed in the sternpost, to hang the rudder. See HELM.

PINTOR (Peter), born at Valentia in Spain, in the year 1420, was physician to Alexander VI. whom he followed to Rome, where he practised with great success. He has left behind him two performances of considerable merit, 1. *Aggregator Sententiarum Doctorum de Curatione in Pestilentia*, printed at Rome 1499, in folio. 2. *De Morbo Fado & Occulto his Temporibus Affligenti*, &c. printed at Rome, 1500. in 4to, black letter; a book extremely scarce, unknown to Lullini and Astruc, and which traces the venereal disease to the year 1460. Pintor died at Rome in 1503, aged 83 years.

PINTURICCIO (Bernardino), a celebrated Italian painter, born at Perugia in 1454. He was the disciple of Peter Perugino, under whom he became so good an artist, that he employed him on many occasions as his assistant. He principally painted history and grotesque; but he also excelled in portraits, among which those of pope Pius II. and Innocent VIII. of Giulia Farnese, Cæsar Borgia, and queen Isabella of Spain, are particularly distinguished. The most memorable performance of Pinturiccio is the history of Pius II. painted in ten compartments in the history of Siena; in which undertaking, Raphael, then a young man and bred under the same master, assisted him so far as to sketch out cartoons of many parts of the composition. The story of his death is worth relating, especially as it illustrates his character. The last work he was engaged in was a *Nativity* for the monastery of St Francis at Siena: the monks accommodated him with a chamber to work in, which they cleared of all the furniture, except one old trunk or chest that appeared too rotten to move; but Pinturiccio, naturally positive and peevish, insisting on its being taken away, the monks willing to gratify him, complied. It was no sooner stirred than one of the planks bursting, out tumbled 500 pieces of gold, which had been secreted there for many years. The monks were overjoyed at finding this treasure, and the painter proportionably mortified at losing his chance of the discovery by his indiscreet obstinacy: it affected his spirits so much he survived but a few months, and it was that generally considered as the cause of his death.

PINUS, the PINE-TREE; a genus of the monodelphia order, belonging to the monœcia class of plants. The pine-tree was well known to the ancients, and has been described and celebrated both by their philosophers and poets. Pliny enumerates no less than six species of trees of this genus; and it is mentioned by Virgil both in his *Eclogues*, his *Georgics*, and his *Æneid*; by Horace in his *Odes*; by Ovid in his *Metamorphoses*; by Statius; and by Catullus, &c. Macrobius relates a pleasant anecdote concerning the cones

Pintada
||
Pinus.

Pinus. of pine-trees, which in common language were called *poma pinæ*, "pine apples." There lived in the Augustan age one Vatinus, who by some means had irritated the Roman people so much that they pelted him with stones. When he entertained them with gladiators, to save himself from such treatment for the future he procured an edict from the cæsar, that no person should throw any thing but apples in the amphitheatre. It accidentally happened that at this time Cæcellius, eminent for his wit as well as knowledge of the law was consulted on the question, whether a pine-apple (the cone of the pine) was legally included in the term *pomum*, "an apple?" It is an apple (said he) if you intend to fling it at Vatinus*. A decision by which the edict in his favour did not much mend his situation: for Martial represents it dangerous to come under this tree, because the cones in his time were of so great a size and weight, probably enlarged by cultivation for ages.

Nuces Pineæ.

*Poma sumus Cypæis: procul hinc disicite, viator,
Nec cadat in viscerum nostrorum ruina caput †.*

There are generally reckoned 14 species of this genus; of which the most remarkable are these following:

1. The *pinæ pinæ*, or wild pine, grows naturally on the mountains in Italy and the south of France. It grows to the size of a large tree; the branches extend to a considerable distance; and while the trees are young, they are fully garnished with leaves, especially where they are not so close as to exclude the air from those within; but as they advance in age, the branches appear naked, and all those which are situated below become unlighty in a few years; for which reason they are now much less in esteem than formerly.

2. The *pinus pinea*, or stone pine, is a tall evergreen tree, native of Italy and Spain. It delights in a sandy loam, though like most others it will grow well in almost any land. Respecting the uses of this species, Hanbury tells us that "the kernels are eatable, and by many preferred to almonds. In Italy they are served up at table in their deserts.—They are exceeding wholesome, being good for coughs, colds, consumptions, &c. on which account only this tree deserves to be propagated." Hanbury continues: "It may be very proper here to take notice of a very great and dangerous mistake Mr Miller has committed, by saying, under this article of stone-pine, that seeds kept in the cones will be good and grow if they are sown ten or twelve years after the cones have been gathered from the trees; whereas the seeds of this sort, whether kept in the cones or taken out, are never good after the first year; and though sometimes a few plants will come up from the seeds that are kept in the cones from two years before, yet this is but seldom; neither must a tenth part of a crop be expected. This caution is the more necessary, as several gentlemen who had cones, upon reading Mr Miller's book, and finding the seeds would take no damage when kept there, deferred the work for a season or two, when they thought they should have more conveniency either of men or ground for their purpose; and were afterwards wholly disappointed, no plants appearing, the seeds being by that time spoiled and worth nothing."

VOL. XIV.

3. The *rubra*, commonly called the *Silberfir* or *pinus*. It is common throughout Scotland, where it is called *pinus*; though it is also found in most of the other countries of Europe. M. du Hamel, of the Royal Academy of Sciences, mentions his having received some seeds of it from St Domingo in the West Indies; and this he concludes, that it grows indifferently in the temperate, frigid, and torrid zones. The wood of this tree is the red or yellow deal, which is the most durable of any of the kinds yet known. The leaves of this tree are much shorter and broader than those of the former sort, of a greyish colour, growing two out of one sheath; the cones are small, pyramidal, and end in narrow points; they are of a light colour, and the seeds are small.

4. The *pinus picea*, or yew-leaved fir, is a tall evergreen and a native of Scotland, Sweden, and Germany. This species includes the silver fir and the balm of Gilead fir. The first of these is a noble upright tree. Mr Marham says, "The tallest trees I have seen were spruce and silver firs in the valleys in Switzerland. I saw several firs in the dookyards in Venice 40 yards long; and one of 39 yards was 15 inches diameter at the small end. I was told they came from Switzerland."

The branches are not very numerous, and the bark is smooth and delicate. The leaves grow singly on the branches, and their ends are slightly indented. Their upper surface is of a fine strong green colour, and their under has an ornament of two white lines running lengthwise on each side the midrib: on account of which silvery look this sort is called the *silber fir*. The cones are large, and grow erect; and, when the warm weather comes on, they soon shed their seeds; which should be a caution to all who wish to raise this plant, to gather the cones before that happens.

The balm of Gilead fir has of all the sorts been most coveted, on account of the great fragrance of its leaves; though this is not its only good property: for it is a very beautiful tree, naturally of an upright growth, and the branches are so ornamented with their balmy leaves, as to exceed any of the other sorts in beauty. The leaves, which are very closely set on the branches, are broad; and their ends are indented. Their upper surface, when healthy, is of a fine dark-green colour, and their under has white lines on each side the midrib lengthwise, nearly like those of the silver fir. These leaves when bruised are very finely scented; and the buds, which swell in the autumn for the next year's shoot, are very ornamental all winter, being turgid, and of a fine brown colour: and from these a soft exudes a kind of fine turpentine, of the same kind of (though heightened) fragrant. The tree being wounded in any part, emits plenty of this turpentine; and Hanbury says, "it is supposed by many to be the sort from whence the balm of Gilead is taken, which occasions this tree being so called. But this is a mistake; for the true balm of Gilead is taken from a kind of terebinthus: though I am informed, that what has been collected from this tree has been sent over to England from America (where it grows naturally), and often sold in the shops for the true sort."

The silver fir is very hardy, and will grow in any soil or situation, but always makes the greatest progress in rich loamy earth. The balm of Gilead fir must be planted in deep, rich, good earth; nor will it live long

* Saturn.

cap. 6.

† Lib. 13,
Ep. 25.

Pinus. in any other. The soil may be a black mould, or of a sandy nature, if it be deep enough, and if the roots have room enough to strike freely.

5. The *pinus abies*, or European spruce fir, a native of the northern parts of Europe and of Asia, includes the Norway spruce and long-coned Cornish fir. The former of these is a tree of as much beauty while growing as its timber is valuable when propagated on that account. Its growth is naturally like the silver, upright: and the height it will attain to may be easily conceived, when we say that the white deal, so much coveted by the joiners, &c. is the wood of this tree; and it may perhaps satisfy the curious reader to know, that from this fir pitch is drawn. The leaves are of a dark green colour; they stand singly on the branches, but the younger shoots are very closely garnished with them. They are very narrow; their ends are pointed; and they are possessed of such beauties as to excite admiration. The cones are eight or ten inches long, and hang downwards.

The better the soil is, the faster will the spruce fir grow, though it will thrive very well in most of the English lands. In strong loamy earth it makes a surprising progress; and it delights in fresh land of all sorts, which never has been worn out by ploughing, &c. though it be ever so poor. The long-coned Cornish fir differs scarcely in any respect from the Norway spruce, except that the leaves and the cones are larger.

6. The *pinus Canadensis*, American or Newfoundland spruce fir, a native of Canada, Pennsylvania, and other parts of North America, includes three varieties. The white Newfoundland spruce, the red Newfoundland spruce, and the black Newfoundland spruce. These, however, differ so little, that one description is common to them all. They are of a genteel upright growth, though they do not shoot so freely or grow so fast in Britain as the Norway spruce. The leaves are of the same green, and garnish the branches in the same beautiful manner as those of that species; only they are narrower, shorter, and stand closer. The greatest difference is observable in the cones; for these are no more than about an inch in length, and the scales are closely placed. In the cones, indeed, consists the difference of these three sorts: those of the white species are of a very light brown colour; those of the red species more of a nut brown or reddish colour; and those of the black species of a dark or blackish colour. Besides this, there is scarcely any material difference; though it is observable, that this trifling variation seems to be pretty constant in the plants raised from the like seeds. These sorts will often flower, and produce cones when only about five or six feet high: and indeed look then very beautiful: but this is a sign of weakness in the plant, which it does not often fairly get over.

7. The *pinus balsamea*, or hemlock fir, a native of Virginia and Canada, possesses as little beauty as any of the fir tribe; though, being rather scarce in proportion, it is deemed valuable. It is called by some the *yew-leaved fir*, from the resemblance of the leaves to those of the yew-tree. It is a tree of low growth, with but few branches; and these are long and slender, and spread abroad without order. The leaves do not garnish the branches so plentifully as those of any other sort of fir. The cones are very small and rounded; they are about

half an inch long; and the scales are loosely arranged. They are sent from America to Europe, by which plants are raised; though this caution should be given to the planter, that this tree is fond of moist rich ground, and in such a kind of soil will make the greatest progress.

8. The *pinus orientalis*, or oriental fir, a native of the East, is a low but elegant tree. The leaves are very short and nearly square. The fruit is exceeding small, and hangs downward; and the whole tree makes an agreeable variety with the other kinds.

9. The *Strobus*, Lord Weymouth's pine, or North American white pine. This grows sometimes to the height of 100 feet and upwards, and is highly valued on account of its beauty. The bark of the tree is very smooth and delicate, especially when young; the leaves are long and slender, five growing out of one sheath; the branches are pretty closely garnished with them, and thus make a fine appearance. The cones are long, slender and very loose, opening with the first warmth of the spring; so that if they are not gathered in winter, the scales open and let out the seeds. The wood of this sort is esteemed for making masts for ships. In Queen Anne's time there was a law made for the preservation of these trees, and for the encouragement of their growth in America. Within these last 50 years they have been propagated in Britain in considerable plenty.

With respect to the culture of this species, Mr Hanbury, after some more general directions, continues thus, "I have known gentlemen, who, in attempting to raise these trees, have seen the young plants go off without perceiving the cause; and the more watering and pains they have taken, have found the plants perish in this way more and more, to their great mortification and astonishment. In the spring following these plants should be pricked out in beds half a foot asunder each way; and here they may stand two years, when they may be either finally planted out, or removed into the nursery, at the distance of one foot asunder, and two feet in the rows. If care has been taken of them in the nursery, they may be removed at a considerable height with great assurance of success: for it is much easier to make this pine grow than any of the other sorts: so that where they are wanted for ornament in parks, open places, &c. a show of them may be made in a little time.

"The soil the Weymouth pine delights in most is a sandy loam; but it likes other soils of an inferior nature: and although it is not generally to be planted on all lands like the Scotch fir, yet I have seen it luxuriant and healthy, making strong shoots, on blue and red clays, and other sorts of strong ground. On stony and and stony ground, likewise, I have seen some very fine trees; so that I believe whoever is desirous of having plantations of this pine, need not be curious in the choice of his ground."

10. The *pinus taeda*, or swamp-pine, is a tall evergreen tree, a native of the swamps of Virginia and Canada. There are several varieties of this genus which Hanbury enumerates and describes: such as, 1st, The three-leaved American swamp-pine. 2d, The two-leaved American pine. 3d, The yellow American pine, the yellow tough pine, and the tough pine of the plains;

among

Pinus.

Pinus. among which there is but little variety. 4th, The bastard pine. 5th, The frankincense pine. And, 6th, The dwarf pine.

“There are many (continues our author) other sorts of American pines, which we receive from thence with the like cant names of those of the above, which I have chosen to retain, as they will probably be continued to be sent over; and that the gardener receiving them as such may best know what to do with them. In many of those sorts I see at present no material difference; so am induced to think they are the same, sent over with different names. Some of the sorts abovementioned differ in very few respects; but I have chosen to mention them, as a person may be supplied with the seeds from Pennsylvania, Jersey, Virginia, Carolina, &c. where they all grow naturally: and having once obtained the seeds, and from them plants, they will become pleasing objects of his nicest observations.”

11. The *pinus cedrus*, ranked by Tournefort and others under *larix*, famous for its duration, is that popularly called by us the *cedar of Lebanon*, by the ancients *cedrus magna* or the *great cedar*; also *cedrelate*, *κεδρελάτη*; and sometimes the Phœnician or Syrian cedar, from the country where it grows in its greatest perfection. It is a coniferous evergreen, of the bigger sort, bearing large roundish cones of smooth scales, standing erect, the leaves being small, narrow, and thick set.—They sometimes counterfeit cedar, by dying wood of a reddish hue: but the smell discovers the cheat, that of true cedar being very aromatic. In some places, the wood of the cajou-tree passes under the name of cedar, on account of its reddish colour and its aromatic smell, which somewhat resemble that of *fantal*. Cedar-wood is reputed almost immortal and incorruptible; a prerogative which it owes chiefly to its bitter taste, which the worms cannot endure. For this reason it was that the ancients used cedar tablets to write upon, especially for things of importance, as appears from that expression of Persius, *Et cedra digna locutus*. A juice was also drawn from cedar, with which they smeared their books and writings, or other matters, to preserve them from rotting; which is alluded to by Horace: by means of which it was that Numa's books, written on papyrus, were preserved entire to the year 535, as we are informed by Pliny.

Solomon's temple, as well as his palace, were both of this wood. That prince gave king Hiram several cities for the cedars he had furnished him on these occasions. Cortes is said to have erected a palace at Mexico, in which were 7000 beams of cedar, most of them 120 feet long, and twelve in circumference, as we are informed by Herrera. Some tell us of a cedar felled in Cyprus 130 feet long, and 18 in diameter. It was used for the main-mast in the galley of king Demetrius. Le Bruyn assures us, that the two biggest he saw on mount Lebanon, measured, one of them 57 palms, and the other 47, in circumference. In the temple of Apollo at Utica, there were cedar trees near 2000 years old; which yet were nothing to that beam in an oratory of Diana at Seguntum in Spain, said to have been brought thither 200 years before the destruction of Troy. Cedar is of a dry a nature, that it will not endure to be fastened with iron nails, from

which it usually shrinks; so that they commonly fasten it with pins of the same wood.

“The statue (says Harbury) of the great goddess at Ephesus was made of this material; and, if this tree abounded with us in great plenty, it might have a principal share in our most superb edifices. The essences constantly emitted from its wood are said to purify the air, and make rooms wholesome. Chapels and places set apart for religious duties, being wainscoted with this wood, inspire the worshippers with a more solemn awe. It is not obnoxious to worms; and emits an oil which will preserve either books from worms or corruption. The saw-dust will preserve human bodies from putrefaction: and is therefore said to be plentifully used in the rites of embalming, where practised.”

It is remarkable that this tree is not to be found as a native in any other part of the world than mount Libanus, as far as hath yet been discovered. What we find mentioned in Scripture of the lofty cedars can be nowise applicable to the common growth of this tree; since, from the experience we have of those now growing in England, as also from the testimony of several travellers who have visited those few remaining trees on mount Libanus, they are not inclined to grow very lofty, but on the contrary extend their branches very far; to which the allusion made by the Psalmist agrees very well, when he is describing the flourishing state of a people, and says, “They shall spread their branches like the cedar-tree.”

Rauwolf, in his Travels, says, there were not at that time (i. e. anno 1574) upon mount Libanus more than 26 trees remaining, 24 of which stood in a circle; and the other two, which stood at a small distance, had their branches almost consumed with age; nor could he find any younger tree coming up to succeed them, though he looked about diligently for some. These trees (he says) were growing at the foot of a small hill, on the top of the mountains, and amongst the snow. These having very large branches, commonly bend the tree to one side, but are extended to a great length, and in so delicate and pleasant order, as if they were trimmed and made even with great diligence, by which they are easily distinguished, at a great distance, from fir-trees. The leaves (continues he) are very like to those of the larch-tree, growing close together in little branches upon small brown shoots.

Maundrel, in his Travels, says, there were but 16 large trees remaining when he visited the mountain, some of which were of a prodigious bulk, but that there were many more young ones of a smaller size: he measured one of the largest, and found it to be 12 yards six inches in girth, and yet found, and 37 yards in the spread of its boughs. At about five or six yards from the ground it was divided into five limbs, each of which was equal to a great tree. What Maundrel hath related was confirmed by a gentleman who was there in the year 1720, with this difference only, viz. in the dimensions of the branches of the largest tree, which he measured, and found to be 22 yards diameter. Now, whether Mr Maundrel meant 37 yards in circumference of the spreading branches, or the diameter of them, cannot be determined by his

Pinus. woods; yet either of them well agrees with this last account.

12. There is another species, viz. the *larch-tree*, which the old botanists ranked under *larix*, with deciduous leaves, and oval obtuse cones. It grows naturally upon the Alps and Apennines, and of late has been very much propagated in Britain. It is of quick growth, and the trunk rises to 50 feet or more; the branches are slender, their ends generally hanging downward, and are garnished with long narrow leaves which arise in clusters from one point, spreading open above like the hairs of a painter's brush: they are of a light green, and fall away in autumn. In the month of April the male flowers appear, which are disposed in form of small cones; the female flowers are collected into oval obtuse cones, which in some species have bright purple tops, and in others they are white: these differences are accidental; the cones are about an inch long, obtuse at their points; the scales are smooth, and lie over each other: under each scale there are generally lodged two seeds, which have wings. There are other two varieties of this tree, one of which is a native of America, and the other of Siberia. The cones of the American kind which have been sent to Britain seem in general to be larger than those of the common sort.

“Many encomiums (says Haubury when speaking of this species) have been bestowed on the timber of the larch: and we find such a favourable account of it in ancient authors, as should induce us to think it would be proper for almost any use. Evelyn recites a story of Witsen, a Dutch writer, that a ship built of this timber and cypress had been found in the Numidian sea, twelve fathoms under water, found and entire, and reduced to such a hardness as to resist the sharpest tool, after it had lain submerged above 1400 years. Certain it is this is an excellent wood for ship and house-building. At Venice this wood is frequently used in building their houses, as well as in Switzerland, where these trees abound: so that, without all doubt, the larch excels for masts for ships, or beams for houses, doors, windows, &c. particularly as it is said to resist the worm.

“In Switzerland (A) their houses are covered with boards of this wood cut out a foot square: and, as it emits a resinous substance, it so diffuses itself into every joint and crevice, and becomes so compact and close, as well as so hardened by the hair, as to render the covering proof against all weather. But as such covering for houses would cause great devaluation in case of fire, the buildings are confined to a limited distance by an order of police from the magistrates. The wood, when first laid on the houses, is said to be very white: but this colour, in two or three years is changed, by means of the sun and resin, to a black, which appears like a smooth shining varnish.”

Of the common larch there are several varieties. The flowers which the commonest sort exhibits early in the spring are of a delicate red colour; another sort produces white flowers at the same season, and these have a delightful effect among those of the red sort; whilst another, called the *Black Newfoundland larix*, increases the variety, though by an aspect little differing from the others. There are also larches with greenish flowers, pale red, &c. all of which are accidental varieties from seeds. These varieties are easily distinguished, even when out of blow: the young shoots of the white-flowering larch are of the lightest green, and the cones when ripe are nearly white. The red flowering larch has its shoots of a reddish cast, and the cones are of a brown colour; whilst the cones and shoots of the black Newfoundland larch are in the same manner proportionally tinged. The cones, which are a very great ornament to several sorts of the pines, are very little to these. Their chief beauty consists in the manner of their growth, the nature and beauty of their pencilled leaves and fair flowers; for the cones that succeed them are small, of a whitish, a reddish, or a blackish brown colour, and make no figure.

The *pinus cedrus* and *pinus larix* are propagated by sowing in March on a bed of light earth exposed to the morning sun. The seed must be covered half an inch thick with fine light earth, and the beds watered at times when the weather is dry. In about six weeks the plants will appear; they must at this time be carefully guarded from the birds, shaded from the sun and winds, and kept very clear of weeds. In the latter end of April the following year, they may be removed into beds of fresh earth, placing them at ten inches distance every way. They are to be kept here two years, and such of them as seem to bend must be tied up to a stake to keep them upright. They may afterwards be planted in the places where they are to remain. They thrive well on the sides of barren hills, and make a very pretty figure there.

Respecting the uses of this tree, Dr Pallas, in his *Flora Rossica* informs us, that if it is burnt, and the wood consumed, the internal part of the wood distils copiously a drying reddish gum, a little less glutinous than gum arabic, somewhat of a resinous taste, but wholly soluble in water. At the instigation of M. Kinder, this gum has lately been sold in the Russian shops under the name of *gummi Orenburgense*, but which our author thinks should be called *gummi waliense* or *laricis*. It is cat by the Woguli as a daisy, and is said to be nutritious and antiscorbutic. Some manna was gathered from the green leaves, but it could never be condensed. The Russians use the *boletus larcinus* as an emetic in intermittents, and to check the leucorrhœa. At Bafchir and Siberia the inhabitants sprinkle the dry powder on the wounds of oxen and horses, as a detergent and anthelmintic.

The

(A) “Between Bex and Devieux (says Coxe in his *Travels in Switzerland*), I observed the larch in great plenty. Painters, from the time of Pliny to which the Roman naturalist styles *immortale lignum*. The wood is reckoned excellent for all works which are to lie under water: and the borderers on the lake of Geneva prefer it for building their vessels. In these parts I saw most beautiful woods of chestnut. Haller says that they extend some leagues; he also informs us, that they are found in other parts of Switzerland, and even in desert places in some of the transalpine parts. Accident must have brought them thither, as it appears from Pliny that these trees were first introduced into Europe from Sardis.”

Pinus. The nuts of the *pinus cembra*, the same author asserts, are cat as luxuries in Russia, and are even exported with the same view. The unripe cones give a very fragrant oil, termed balsamic. The inhabitants of Siberia use the tender tops, and even the bark rubbed off in the spring, as an antiscorbutic. The kernels of the nuts of the *amygdalus nana* give a very pleasing flavour to brandy; and, when pressed, afford a bitter oil in large quantities. The way of destroying the bitter is by digesting it in the sun with spirit of wine, and it then becomes sweet and extremely agreeable.

From the larch-tree is extracted what we erroneously call *Venice turpentine*. This substance, or natural balsam, flows at first without incision; when it has done dropping, the poor people who wait in the fir woods make incisions at about two or three feet from the ground into the trunks of the trees, into which they fix narrow troughs about 20 inches long. The end of these troughs is hollowed like a ladle; and in the middle is a small hole bored for the turpentine to run into the receiver which is placed below it. As the gummy substance runs from the trees, it passes along the sloping gutter or trough to the ladle, and from thence runs through the holes into the receiver. The people who gather it visit the trees morning and evening from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, Venice turpentine is clear like water, and of a yellowish white; but, as it grows older, it thickens and becomes of a citron colour. It is procured in the greatest abundance in the neighbourhood of Lyons, and in the valley of St Martin near St Lucern in Switzerland.

Though we have already noticed the manner of cultivating some of the particular species of this genus, and have also remarked the uses of some of them, we shall finish the article with a few general observations on the culture and uses of the whole.

Culture. All the sorts of pines are propagated by seeds produced in hard woody cones. The way to get the seeds out of these cones is to lay them before a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good for some years; so that the surest way of preserving them is to let them remain in the cones till the time for sowing the seeds. If the cones are kept in a warm place in summer, they will open and emit the seeds; but if they are not exposed to the heat, they will remain close for a long time. The best season for sowing the pines is about the end of March. When the seeds are sown, the place should be covered with the nets to keep off the birds; otherwise, when the plants begin to appear with the hulk of the seed on the top of them, the birds will peck off the tops, and thus destroy them.

Uses. From the first species is extracted the common turpentine, much used by farriers, and from which is drawn the oil of that name. The process of making pitch, tar, resin, and turpentine, from these trees is very familiar. In the spring time, when the sap is most free in running, they pare off the bark of the pine tree, to make the sap run down into a hole which they cut at the bottom to receive it. In the way, as it runs down, it leaves a white matter like cream, but

a little thicker. This is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of *Banbanax* instead of white bees wax. The matter that is received in the hole at the bottom is taken up with ladles, and put in a large basket. A great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, adding a large quantity of water. They distil this as long as any oil is seen swimming upon the water. This oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine. The remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all that they can from the sap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with these billets, and, setting them on fire, there runs from them, while they are burning, a black thick matter. This naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil. If this hole be made too large, it sets the whole quantity of the tar on fire; but, if small enough, it runs quietly out.

The tar, being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it. It is then suffered to boil a while, and being then let out, is found when cold to be what we call pitch.

A decoction of the nuts or seeds of the first species in milk, or of the extremities of the branches pulled in spring, is said, with a proper regimen, to cure the most inveterate scurvy. The wood of this species is not valued; but that of the Scots pine is superior to any of the rest. It is observed of the Scots pine, that when planted in bogs, or in a moist soil, though the plants make great progress, yet the wood is white, soft, and little esteemed; but when planted in a dry soil, though the growth of the trees is there very slow, yet the wood is proportionably better. Few trees have been applied to more uses than this. The tallest and straightest are formed by nature for masts to the navy. The timber is resinous, durable, and applicable to numberless domestic purposes, such as flooring and wainscoting of rooms, making of beds, chests, tables, boxes, &c. From the trunk and branches of this, as well as most others of the pine tribe, tar and pitch is obtained. By incision, *barras*, Burgundy pitch, and turpentine, are acquired and prepared. The resinous roots are dug out of the ground in many parts of the Highlands, and, being divided into small splinters, are used by the inhabitants to burn instead of candles.—At Loch-Broom, in Ross-shire, the fishermen make ropes of the inner bark; but hard necessity has taught the inhabitants of Sweden, Lapland, and Kamtschka, to convert the same into bread. To effect this, they, in the spring season, make choice of the tallest and fairest trees; then stripping off carefully the outer bark, they collect the soft, white, succulent interior bark, and dry it in the shade. When they have occasion to use it, they first toast it at the fire, then grind, and af-

Pioneers
||
Pipe.

ter sleeping the flour in warm water to take off the resinous taste, they make it into thin cakes, which are baked for use. On this strange food the poor inhabitants are sometimes constrained to live for a whole year; and, we are told, through custom become at last even fond of it. Linnaeus remarks, that this same bark-bread will fatten swine; and humanity obliges us to wish, that men might never be reduced to the necessity of robbing them of such a food. The interior bark, of which the abovementioned bread is made, the Swedish boys frequently peel off the trees in the spring, and eat raw with greedy appetite. From the cones of this tree is prepared a diuretic oil, like the oil of turpentine, and a resinous extract, which has similar virtues with the balsam of Peru. An infusion or tea of the buds is highly commended as an antiscorbutic. The farina, or yellow powder, of the male flowers, is sometimes in the spring carried away by the winds, in such quantities, where the trees abound, as to alarm the ignorant with the notion of its raining brimstone. The tree lives to a great age; Linnaeus affirms to 400 years.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army for mending the ways, for working on intrenchments and fortifications, and for making mines and approaches. The English soldiers are likewise employed for all these purposes. Most of the foreign regiments of artillery have half a company of pioneers, well instructed in that important branch of duty. Some regiments of infantry and cavalry have three or four pioneers each, provided with aprons, hatchets, saws, spades, and pick-axes. Each pioneer must have an ax, a saw, and an apron; a cap with a leather crown, and a black bears-skin front, on which is to be the king's crest in white, on a red ground; and the number of the regiment is to be on the back part of it.

PIP, or PEP, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding. It usually arises from want of water, or from the drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with salt. Hawks are particularly liable to this disease, especially from feeding on stinking flesh.

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other liquids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are usually made of oak or elder. Those of iron are cast in forges; their usual length is about two feet and a half: several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them together, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augres, of different sizes, beginning with a lets, and then proceeding with a larger successively; the first being pointed, the rest being formed like spoons, increasing in diameter, from one to six inches or more: they are fitted into the ex-

trimities of each other (as represented fig. 2.), and are sold by the foot.

Wooden pipes are bored as follows. The machine represented fig. 1. is put in motion by the wheel A, which is moved by a current of water; upon the axle of this wheel is a cog wheel B, which causes the lanterns C, D, to turn horizontally, whose common axis is consequently in a perpendicular direction. The lantern D turns at the same time two cog-wheels, E and F: the first, E, which is vertical, turns the augre which bores the wood; and the second, F, which is horizontal, causes the carriage bearing the piece to advance by means of the arms H, I, which takes hold of the notches in the wheel K. The first, H, by means of the notches, draws the wheel towards F; and the other, I, pushes the under-post of the wheel in an opposite direction; both which motions tend to draw the carriage towards F, and consequently cause the augre to pierce the wood. The augre being from 9 to 12 feet in length, and of a proportionable bigness, it will be necessary to have two pieces, as L, L, to support its weight, and cause it to enter the piece to be bored with the same uniformity.

For the construction of leaden pipes, see the article PLUMBERY.

Air-PIPES. See *Air-Pipes*.

PIPES of an Organ. See *ORGAN*.

Bag-PIPE. See *Bag-Pipe*.

Horn-PIPE. See *HORN-PIPE*.

Tobacco-PIPE, a machine used in the smoking of tobacco, consisting of a long tube, made of earth or clay, having at one end a little case, or furnace, called the *bowl*, for the reception of the tobacco, the fumes whereof are drawn by the mouth through the other end. Tobacco-pipes are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use pipes three or four feet long, made of rushes, or of wood bored, at the end whereof they fix a kind of a pot of baked earth, which serves as a bowl, and which they take off after smoking.

PIPE, also denotes a vessel or measure for wine, and things measured by wine-measure. See *BARREL* and *MEASURE*.

PIPE, in mining, is where the ore runs forwards endwise in a hole, and doth not sink downwards or in a vein.

PIPE, *Pipa*, in law, is a roll in the exchequer, called also the *great roll*. See the next article.

Pipe-Office, in England, is an office wherein a person called the *clerk of the pipe*, makes out leases of crown-lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer. The clerk of the pipe makes out also all accounts of sheriffs, &c. and gives the accountants their *quietus est*. To this office are brought all accounts which pass the remembrancer's office, and remain there, that if any stated debt be due from any person, the same may be drawn down into the great roll of the pipe: upon which the comptroller issues out a writ, called the *summons of the pipe*, for recovery thereof; and if there be no goods or chattels, the clerk then draws down the debts to the lord-treasurer's remembrancer, to write estreats against their lands. All tallies which vouch

the payment of any sum contained in such accounts are examined and allowed by the chief secondary of the pipe. Besides the chief clerk in this office, there are eight attorneys or sworn clerks, and a comptroller.

Pipe Fish, in ichthyology. See SYNGNATHUS.

Sea-Pipes, in zoology, are univalve shells, of an oblong figure, terminating in a point, sometimes a little bending, and sometimes straight. Sea ears, figures of which we have given along with the sea-pipes, are also univalve flat shells, resembling in shape the ear of a man. In sea ears it is not uncommon to find small pearls, the seeds of which are often found in the middle of their cavities, which are of the finest naker or mother-of-pearl colour. There are ridges on both sides; these without form a kind of volute or spire, terminating in an eye. In these shells there is a row of round holes, six of which generally go quite through.

There is a shell of this kind, which is longer in proportion to its width, and much less common. There is yet another, very fine and thin, of a dirty grey colour, neither nakered nor perforated as the others are; the inner rim is spiral, and at some distance from the outer.

The sea-pipes are distinguished from sea-worms by having their pipes single; whereas the others form an assemblage of pipes joined together. The sea worms, from the number and junction of their parts, are multivalves. The shells of pipes called *dentales* and *antales* are distinguished from each other only by their size, the antales being much the least. The *sea pencil*, or *watering spout*, is the most remarkable shell of this tribe, and must be considered as having a specific character either by its form, which is straight, or the singularity of its superior extremity, which is perforated like the spout of a watering pot.

In Plate CCCXCII. the shell, fig. 1. pierced with many holes, is found with its natural covering. It is finely nakered within, and in the middle of its hollow or cavity contains many small pearls. Fig. 2. is placed on its upper side to show its spots, which are red upon a ground of the purest white; the ridges are prominent; the rim and the eye are irregular and notched. Fig. 4. the singularity of this shell consists in its being neither nakered nor perforated, and in turning very much up near the eye of its spire or contour. Fig. 5. is a pencil or watering spout; at the head is a kind of ruff, and within it is formed like the end of a watering spout, perforated with many holes, which, when the fish is alive, are filled with very fine threads, like the hairs of a painter's pencil. Fig. 6. are called dentals from their resemblance of elephants teeth; the point or apex is white, and the other extremity green. They are both ribbed and nakered, and are distinguished from each other only by some excrescences which appear on the uppermost. Fig. 7. are two small shells of the dental figure, called for distinction antales. They are perfectly smooth; one is white, and the other reddish.

PIPER, in ichthyology. See TRIGLA.

PIPER, *Piper*: a genus of the trigyna order, belonging to the diandria class of plants. There are 20 species, of which the most remarkable is the fibrous, with oval, heart-shaped, nerved leaves, and reflexed spikes. This is the plant which produces the pepper so much used in food. It is a shrub whose root is small, fibrous, and flexible; it rises into a stem, which requires a tree or a prop to support it. Its wood has the same sort of knots as the vine; and when it is dry, it exactly resembles the vine-branch. The leaves, which have a strong smell and a pungent taste, are of an oval shape; but they diminish towards the extremity, and terminate in a point. From the flower-buds, which are white, and are sometimes placed in the middle and sometimes at the extremity of the branches, are produced small berries resembling those of the currant-tree. Each of these contains between 20 and 30 corns of pepper; they are commonly gathered in October, and exposed to the sun seven or eight days. The fruit, which was green at first, and afterwards red, when stripped of its covering assumes the appearance it has when we see it. The largest, heaviest, and least shrivelled, is the best.

The pepper plant flourishes in the islands of Java, Sumatra (A), and Ceylon, and more particularly on the Malabar coast. It is not sown, but planted; and great nicety is required in the choice of the shoots. It produces no fruit till the end of three years; but bears so plentifully the three succeeding years, that some plants yield between six and seven pounds of pepper. The bark then begins to shrink; and the shrub declines so fast, that in 12 years time it ceases bearing.

The culture of pepper is not difficult: it is sufficient to plant it in a rich soil, and carefully to pull up the weeds that grow in great abundance round its roots, especially the three first years. As the sun is highly necessary to the growth of the pepper plant, when it is ready to bear, the trees that support it must be lopped to prevent their shade from injuring the fruit. When the season is over, it is proper to crop the head of the plant. Without this precaution, there would be too much wood, and little fruit.

The pepper exported from Malabar, which was formerly entirely in the hands of the Portuguese, and is at present divided between the Dutch, British, and French, amounts to about 10,000,000 weight. Betel, or betle, is a species of this genus. See BETEL. It is a creeping and climbing plant like the ivy; and its leaves a good deal resemble those of the citron, though they are longer and narrower at the extremity. It grows in all parts of India, but thrives best in moist places. The natives cultivate it as we do the vine, placing props for it to run and climb upon; and it is a common practice to plant it against the tree which bears the areca nut.

At all times of the day, and even in the night, the Indians chew the leaves of the betel, the bitterness of which is corrected by the areca that is wrapped up in them. There is constantly mixed with it the chinam, a kind of burnt lime made of shells. The rich frequently

ly

Piper,
Pipra.

fy add perfumes, either to gratify their vanity or their sensuality.

It would be thought a breach of politeness among the Indians to take leave for any long time, without presenting each other with a purse of betel. It is a pledge of friendship that relieves the pain of absence. No one dares to speak to a stranger unless his mouth is perfumed with betel; it would even be rude to neglect this precaution with an equal. The women of gallantry are the most lavish in the use of betel, as being a powerful incentive to love. Betel is taken after meals; it is chewed during a visit; it is offered when you meet, and when you separate; in short, nothing is to be done without betel. If it is prejudicial to the teeth, it affords and strengthens the stomach. At last, it is a general fashion that prevails throughout India.

The *piper amalago*, or black pepper, and the *piper inepals*, or long pepper of Jamaica, with some other species, are indigeneous, and known by the names of *joint wood*, or *peppery elders*. The first bears a small spike, on which are attached a number of small seeds of the size of mustard. The whole of the plant has the exact taste of the East India black pepper. The long pepper both grows taller than the amalago. The leaves are broad, smooth, and shining. The fruit is similar to the long pepper of the shops, but smaller. The common people in Jamaica season their messes with the black pepper. To preserve both, the fruit may be slightly scalded when green, then dried, and wrapped in paper. Perhaps hereafter they may be deemed worthy of attention.

PIPRA, in ornithology; a genus of birds of the order of *passeres*. Latham gives it the name of *manakin*, and so does Buffon, who informs us that it was bestowed upon them by the Dutch settlers in Surinam. Latham describes 25 different species, and five varieties. The general character of the genus is, that the bill is short, strong, hard, and slightly incurved, and the nostrils are naked. The middle toe is connected to the outer as far as the third joint: this character, however, is not altogether universal, some of the species differing in this particular. The tail is short. This genus has a considerable resemblance to the genus *parus*, or *titmouse*. They are supposed to inhabit South America only; but this is not true, for Mr Latham assures us that he has seen many of those species which he has described which came from other parts, but which nevertheless certainly belong to this genus.—Buffon differs widely in his arrangement from Mr Latham, and only enumerates six distinct species. Without particularizing those differences, however, we shall give from Buffon the following elegant account of the genus in general: "The natural habits common to them all were not known, and the observations which have been made are still insufficient to admit an exact detail. We shall only relate the remarks communicated to us by Sonini of Manoncour, who saw many of these birds in their native climates. They inhabit the immense forests in the warm parts of America, and never emerge from their recesses to visit the cleared grounds on the vicinity of the plantations. They fly with considerable swiftness, but always at a small height, and to a great distance; they never perch on the summits of trees, but on the middle branches; they feed upon

small wild fruits, and almost insects. They generally occur in small bodies of eight or ten of the same species, and sometimes intermingled with other flocks of the same genus, or even of a different genus, such as the Cayenne warblers, &c. It is commonly in the morning that they are found thus assembled, and then seem to be joyous, and warble their delicate little notes. The freshness of the air seems to inspire the song, for they are silent during the burning heat of the day, and disperse and retire to the shade of the thickest parts of the forest. This habit is observable, indeed, in many kinds of birds, and even in those of the woods of France, where they collect to sing in the morning and evening; but the manikins never assemble in the evening, and continue together only from sun-rise to nine or ten o'clock in the forenoon, and remain separate during the rest of the day and the succeeding night. In general they prefer a cool humid situation, though they never frequent marshes or the margins of lakes."

1. The *pipra rufirostris*, or crested manakin, is about the size of a small pigeon, being about 10 or 12 inches long. The bill is about an inch and a quarter long, and of a yellowish colour. The head is furnished with a double round crest; the general colour of the plumage is orange, inclining to saffron; the wing coverts are loose and fringed; the quills are partly white and partly brown; the tail feathers are in number 12; the base half of the ten middle ones is of an orange colour, from thence to the ends they are brown; the outer feathers are brown, and the base half of the inner web is orange; all of them are similarly fringed; the upper tail coverts are very long, loosely webbed, and square at the ends; the legs and claws are yellow. The female is altogether brown, except the under wing coverts, which are of a rufous orange; the crest is neither so complete nor rounded as that of the male. Both males and females are at first grey, or of a very pale yellow, inclining to brown. The male does not acquire the orange colour till the second year, neither does the female the full brown.

"This beautiful species (says Latham), inhabits various parts of Surinam, Cayenne, and Guiana, in rocky situations; but is nowhere so frequent as in the mountain Luca, near the river Oyapoc, and in the mountain Courouaye, near the river Arouack, where they build in the cavernous hollows, and the darkest recesses. They lay two round white eggs, the size of those of a pigeon, and make the nest of a few dry bits of sticks. They are in general very shy, but have been frequently tamed, inasmuch as to run at large among the poultry. It is said that the female, after she has laid eggs for some years, and ceases so to do more, becomes at the ensuing moult of the same colour as the male, and may be mistaken for him; in this imitating the females of various kinds of poultry, such as the peacock, pheasant, &c. (See Pavo, &c.) A most complete pair is in the Leverian Museum." Our author describes a variety of this species, which he calls the *Peruvian manakin*. It is longer than the preceding, especially in the tail, and the upper coverts of it are not truncated at the ends; the wing coverts are not fringed, as in the rock manakin, and the crest is not so well defined as in that bird; the general colour of the plumage inclines much to red; the fe-

cond coverts and rumps are of an ash colour; the wings and tail are black; the bill and legs are as in the bill described. It is an inhabitant of Peru, from whence its name.

2. The next and last species which we shall describe (for it would be impossible to enumerate them all), Mr Latham calls the *tuneful marulin*. Its length is four inches; the bill is dusky, the forehead yellow, and the crown and nape blue; the chin, sides of the head below the eyes, and the throat, are black; the upper part of the back, the wings, and the tail, are dusky black; the tail is very short; the lower part of the back and rump, the breast, belly, vent, and thighs, are orange coloured; the legs are dusky. It is a native of St Domingo, where it has gained the name of *organiste* from its note, forming the complete octave in the most agreeable manner, one note successively after another. It is said not to be uncommon, but not easy to be shot, as, like the creeper, it perpetually shifts to the opposite part of the branch from the spectator's eye, so as to elude his vigilance. It is most likely the very bird mentioned by Du Pratz, above quoted, whose notes, he says, are so varied and sweet, and which warbles so tenderly, that those who have heard it value much less the song of the nightingale. It is said to sing for near two hours without scarce taking breath, and after a respite of about the same time begins again. Du Pratz, who himself has heard it, says that it sung perched on an oak, near the house he was then in.

PIQUET, or TICKET, a celebrated game at cards, much in use throughout the polite world.

It is played between two persons, with only 32 cards; all the ducés, threes, fours, fives and sixes, being set aside.

In reckoning at this game, every card goes for the number it bears, as a ten for ten; only all court cards go for ten, and the ace for eleven; and the usual game is one hundred up. In playing, the ace wins the king, the king the queen, and so down.

Twelve cards are dealt round, usually by two and two; which done, the remainder are laid in the middle; if one of the gamblers finds he has not a court-card in his hand he is to declare he has *carte-blanc*, and tell how many cards he will lay out, and desire the other to discard, that he may show his game, and satisfy his antagonist that the *carte-blanc* is real; for which he reckons ten.

Each person discards, *i. e.* lays aside a certain number of his cards, and takes in a like number from the stock. The first of the eight cards may take three, four, or five; the dealer all the remainder, if he pleases.

After discarding, the eldest hand examines what suit he has most cards of; and reckoning how many points he has in that suit, if the other have not so many in that or any other suit, he tells one for every ten of that suit. He who thus reckons most is said to win the point.

The point being over, each examines what *sequences* he has of the same suit, *viz.* how many tierces, or sequences of three, quintes or fours, quintes or fives, sixes, or six's, &c. For a tierce they reckon three points, for a quarte four; for a quinte 15, for a sixieme 16, &c. And the several sequences are distinguished in dignity by the cards they begin from: thus ace,

king, and queen, are called *tierce majeure*; king, queen, and knave, *tierce to a king*; knave, ten, and nine, *tierce to a knave*, &c. and the best tierce, quinte, or quinte, *i. e.* that which takes its defect from the best card, prevails, so as to make all the others in that hand good, and destroy all those in the other hand. In like manner, a quarte in one hand sets aside a tierce in the other.

The sequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three of any suit, three: but here too, as in sequences, he that with the same number of threes has one that is higher than any the other has; *e. g.* three aces, has all his others made good hereby, and his adversary's all set aside. But four of any sort, which is called a *quatorze*, always sets aside three.

All the game in hand being thus reckoned, the eldest proceeds to play reckoning one for every card he plays above a nine, and the other fellows him in the suit; and the highest card of the suit wins the trick. Note, unless a trick be won with a card above a nine (except the last trick), nothing is reckoned for it: though the trick serves afterwards towards winning the cards; and that he who plays last does not reckon for his cards unless he wins the trick.

The cards being played out, he that has most tricks reckons ten for winning the cards. If they have tricks alike, neither reckons any thing. The deal being finished, and each having marked up his game, they proceed to deal again as before cutting a fresh each time for the deal.

If both parties be within a few points of being up, the *carte-blanc* is the first thing that reckons, then the point, then the sequences, then the quatorzes or threes, then the tenth cards.

He that can reckon 30 in hand by *carte-blanc*, points, quintes, &c. without playing, ere the other has reckoned any thing, reckons 90 for them; and this is called a *repique*. If he reckons above 30, he reckons so many above 90. If he can make up 30, part in hand and part play, ere the other has told any thing, he reckons for them 60. And this is called a *pique*. Whence the name of the game. He that wins all the tricks, instead of ten, which is his right for winning the cards, reckons 40. And this is called a *capot*.

Mr de Moivre, who has made this game the object of mathematical investigations, has proposed and solved the following problems: 1. To find at piquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more. 2. To find at piquet the probability which the eldest has of taking an ace or more in five cards, he having no ace in his hand. Answer; 232 to 91, or 5 to 2, nearly. 3. To find at piquet the probability which the eldest hand has of taking an ace and a king in five cards, he having none in his hand. Answer; the odds against the eldest hand taking an ace and a king are 331 to 315, or 21 to 20 nearly. 4. To find at piquet the probability of having 12 cards dealt to, without king, queen, or knave, which case is commonly called *carte-blanc*. Answer; the odds against *carte-blanc* are 1791 to 1 nearly,

Pira.

nearly. 5. To find how many different sets, essentially different from one another, one may have at piquet before taking in. Answer; 28,967,278. This number falls short of the sum of all the distinct combinations, whereby 12 cards may be taken out of 32, this number being 225,792,840; but it must be considered that in that number several sets of the same import, but differing in suit, might be taken, which would not introduce an essential difference among the sets. The same author gives also some observations on this game, which he had from an experienced player. See *Doctrine of chances*, n. 179, &c. M. de Monmort has treated of piquet in his *Analyse des Jeux de Hazard*, p. 162.

PIRA, is a name by which a variety of foreign fishes are distinguished. The *pira aca* is a little horned fish of the West Indies, called by Clusius and others the *monoceros* or *unicorn fish*. The *pira acangata* is the name of a Brazilian fish, which resembles the perch both in size and shape. It seldom exceeds four or five inches in length; its mouth is small; its tail forked. On the back it has only one long fin, which is supported by rigid and prickly spines. Thus fin it can depress at pleasure, and sink within a cavity made for it in the back. Its scales are of a silvery white colour; it is wholesome and well tasted. *Pira bebe* is the name of the milvus, or kite-fish. *Pira coaba* is an American fish of the truttaceous kind, of a very delicate flavour. It grows to the length of 12 inches; its nose is pointed, and its mouth large, but without teeth; the upper jaw is longer than the under one, and hangs over like a cartilaginous prominence; its eyes are very large, and its tail is forked; under each of the gill fins there is a beard made of six white filaments, and covered with silvery scales. *Pira jurumamba* is a Brazilian fish, otherwise called *bocca molle*. It lives in the muddy bottom of the American seas, and is a long bodied not flattened fish. It grows to a great size, being found nine, and sometimes even ten and eleven, feet long and two feet and a half thick. It has one long fin on the back, the anterior part of which is thin and pellucid. There is also a cavity on the back, as in the *pira acangata*, into which the fin can be depressed at pleasure; the tail is not forked, and the scales are all of a silvery colour and brightness. The fish is very well tasted; the *pira pixanga* is another Brazilian fish of the turdus or wasse kind, and called by some the *gawfish*. It is generally about four or five inches long; its mouth is pretty large, and furnished with very small and very sharp teeth; its head is small, but its eyes are large and prominent, the pupil being of a fine turquoise colour, and the iris yellow and red in a variety of shades. The coverings of the gill's end in a triangular figure, and are terminated by a short spine or prickle; its scales are very small, and so evenly arranged, and closely laid on the flesh, that it is very smooth to the touch; its tail is rounded at the end, its whole body, head, tail, and fins, are of a pale yellow colour, variegated all over with very beautiful blood-coloured spots; these are round, and of the bigness of hemp-seed on the back and sides, and something larger on the belly; the fins are all spotted in the same manner, and are all marked with an edge of red. It is caught among the rocks, and about the shores, and is a very well tasted fish. *Piranka* is an American fish, more generally

known by the name *piraya*. *Pyraquiba*, or *Ipiraquiba*, is the name of a fish originally Brazilian, which some writers apply to the *remora* or *sucking fish*.

PIRÆUS PORTUS, (anc. geog.), a celebrated port to the west of Athens, consisting naturally of three harbours or basins, (Thucydides); which lay neglected, till Themistocles put the Athenians on making it a commodious port, (Nepos); the Phalerus, a small port, and not far from the city, being what they used before that time, (Pausanias, Nepos). Piræus was originally a village of Attica, (Pausanias); an island, (Strabo); and though distant 40 stadia from Athens, was joined to it by two long walls, (Thucydides), and itself locked or walled round, (Nepos): A very commodious and safe harbour. The whole of its compass was 60 stadia, including the Munichia. Not far from the Piræus stood the sepulchre of Themistocles; whither his friends conveyed his bones from Magnesia, into the Hither Asia, (Cicero, Plutarch, Pausanias). The entrance of the Piræus is narrow, and formed by two rocky points, one belonging to the promontory of Ection, the other to that of Aleimus. Within were three stations for shipping; Kantharus, so named from a hero; Aphrodisium, from a temple of Venus; and Zea, the resort of vessels laden with grain. By it was a demos or borough town of the same name before the time of Themistocles, who recommended the exchanging its triple harbour for the single one of Phalerum, both as more capacious and as better situated for navigators. The wall was begun by him when archon, in the second year of the 75th Olympiad, 477 years before Christ; and afterwards he urged the Athenians to complete it as the importance of the place deserved. This whole fortification was of hewn stone, without cement or other material, except lead and iron, which were used to hold together the exterior ranges or facings. It was so wide that the loaded carts could pass on it in different directions; and it was 40 cubits high, which was about half what he had designed.

The Piræus, as Athens flourished, became the common emporium of all Greece. Hippodamus an architect, celebrated, besides other monuments of his genius, as the inventor of many improvements in house building, was employed to lay out the ground. Five porticoes, which uniting formed the *Long Portico*, were erected by the ports. Here was an *agora* or market-place, and, farther from the sea, another called *Hippodamia*. By the vessels were dwellings for the mariners. A theatre was opened, temples were raised, and the Piræus, which surpassed the city in utility, began to equal it in dignity. The cavities and windings of Munichia, natural and artificial, were filled with houses; and the whole settlement, comprehending Phalerum and the ports of the Piræus, with the arsenals, the storehouses, the famous armoury of which Phlo was the architect, and the sheds for 300, and afterwards 400, triemes, resembled the city of Rhodes, which had been planned by the same Hippodamus. The ports, on the commencement of the Peloponnesian war, were secured with chains. Centinels were stationed, and the Piræus was carefully guarded.

The Piræus was reduced with great difficulty by Sylla, who demolished the walls, and set fire to the armoury and arsenals. In the civil war it was in a defenceless condition. Calenus, lieutenant to Cæsar, seized

Piræus.

Chandler's
Travels in
Greece,
p. 19, &c.

Piræus,
Piracy.

seized it, invested Athens, and ravaged the territory. Strabo, who lived under the emperors Augustus and Tiberius, observes, that the many ways had destroyed the long walls, with the towers of Munychia, and had contracted the Piræus into a final settlement by the ports and the temple of Jupiter Saviour. This fabric was then adorned with wonderful pictures, the works of illustrious artists, and on the outside with statues. In the second century, besides houses for triremes, the temple of Jupiter and Minerva remained, with their images in brass, and a temple of Venus, a portico, and the tomb of Themistocles.

The port of the Piræus has been named *Porto Leone* from the marble lion seen in the chart, and also *Porto Draco*. The lion has been described as a piece of admirable sculpture, 10 feet high, and as reposing on its hinder parts. It was pierced, and, as some have conjectured, had belonged to a fountain. Near Athens, in the way to Eleusis, was another, the posture couchant; probably its companion. Both these were removed to Venice by the famous general Morosini, and are to be seen there before the arsenal. At the mouth of the port are two ruined piers. A few vessels, mostly small craft, frequent it. Some low land at the head seems an incroachment on the water. The buildings are a mean custodial use, with a few shops; and by the shore on the east side, a warehouse belonging to the French; and a Greek monastery dedicated to St Spiridion. On the opposite side is a rocky ridge, on which are remnants of the ancient wall, and of a gateway towards Athens. By the water edge are vestiges of building; an inlet going from the customhouse to the city on the right hand, traces of a small theatre in the side of the hill of Munychia.

PIRACY, the crime of robbery and depredation upon the high seas.

By the ancient common law, piracy, if committed by a subject, was held to be a species of treason, being contrary to his natural allegiance; and by an alien, to be felony only: but now, since the statute of treasons, 25 Edw. III. c. 2. it is held to be only felony in a subject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law. But, it being inconsistent with the liberties of the nation, that any man's life should be taken away, unless by the judgment of his peers, or the common law of the land, the statute 28 Hen. VIII. c. 15. established a new jurisdiction for this purpose; which proceeds according to the course of the common law.

The offence of piracy, by common law, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony there. But, by statute, some other offences are made piracy also; as, by statute 11 and 12 W. III. c. 7. if any natural born subject commits any act of hostility upon the high seas, against others of his majesty's subjects, under colour of a commission from any foreign power; this, though it would only be an act of war in an alien, shall be construed piracy in a subject. And farther any commander, or other seafaring person, betraying his trust, and running away with any ship, boat, ordnance, ammunition, or goods; or yielding them up volunta-

rily to a pirate; or conspiring to do these acts; or any person assaulting the commander of a vessel, to hinder him for fighting in defence of his ship; or confining him, or causing or endeavouring to cause a revolt on board; shall for each of these offences, be adjudged a pirate, felon, and robber, and shall suffer death, whether he be principal, or merely accessory by setting forth such pirates, or abetting them before the fact, or receiving or concealing them or their goods after it. And the statute 4 Geo. I. c. 11. expressly excludes the principals from the benefit of clergy. By the statute 8 Geo. I. c. 24. the trading with known pirates, or furnishing them with ammunition, or fitting out any vessel for that purpose, or in any wise consulting, combining, confederating, or corresponding with them, or the forcibly boarding any merchant vessel, though without seizing or carrying her off, and destroying or throwing any of the goods overboard; shall be deemed piracy; and such accessories to piracy as are described by the statute of king William are declared to be principal pirates; and all pirates convicted by virtue of this act are made felons without benefit of clergy. By the same statutes also, (to encourage the defence of merchant vessels against pirates), the commanders or seamen wounded, and the widows of such seamen as are slain, in any piratical engagement, shall be entitled to a bounty to be divided among them, not exceeding one fiftieth part of the value of the cargo on board: and such wounded seamen shall be entitled to the pension of Greenwich hospital; which no other seamen are, except only such as have served in a ship of war. And if the commander shall behave cowardly, by not defending the ship, if she carries guns or arms; or shall discharge the mariners from fighting, so that the ship falls into the hands of pirates; such commander shall forfeit all his wages and suffer six months imprisonment. Lastly, by statute 18 Geo. II. c. 50. any natural born subject or denizen, who in time of war shall commit hostilities at sea against any of this fellow-subjects, or shall assist an enemy on that element, is liable to be tried and convicted as a pirate.

PIRATE, (*πειρατης*, Gr.); a sea-robber, or an armed ship that roams the seas without any legal commission, and seizes or plunders every vessel she meets indiscriminately, whether friends or enemies.

The colours usually displayed by pirates are said to be a black field, with a death's head, a battle-axe, and hour glass. The last instrument is generally supposed to determine the time allowed to the prisoners, whom they take, to consider whether they will join the pirates in their felonious combination, or be put to death, which is often perpetrated in the most cruel manner.

Amongst the most celebrated pirates of the north is recorded Alvilda, daughter of a king of the Goths named *Sypardus*. She embraced this occupation to deliver herself from the violence imposed on her inclination, by a marriage with Alf, son of Sigarus king of Denmark. She dressed herself as a man; and composed her band of rowers, and the rest of her crew, of a number of young women attired, in the same manner. Amongst the first of her cruizes, she touched at a place where a company of pirates bewailed the

Piracy,
Pirate.

Pirone
||
Piron.

death of their captain. The strangers were captivated with the agreeable manners of Alvilda, and chose her for their chief. By this reinforcement she became so formidable upon the sea, that prince Alf came to engage her. She sustained his attacks for a considerable time; but, in a vigorous action, Alf boarded her vessel, and having killed the greatest part of her crew, seized the captain, namely herself; whom nevertheless he knew not, because the prince's had a casque which covered her visage. Being master of her person, he removed the casque; and in spite of her disguise, instantly recognized her, and offered her his hand in wedlock.

PIRENE, (Pliny); a fountain sacred to the muses, springing below the top of the Acrocorinthus, a high and steep mountain which hangs over Corinth. Its waters were agreeable to drink, (Pausanias); extremely clear, (Strabo); very light, (Athenæus); and pale, (Petrus); having relation either to the grief of Pirene, mother of Cenchrea, from whose tears this fountain arose, (Pausanias); or to the paleness brought on by the too eager pursuits of the muses.

PIROMALLI (Paul), a dominican of Calabria was sent a missionary into the east. He remained a long time in Armenia, where he had the happiness to bring back to the church many schismatics and Eutychians, and the patriarch himself, who had before thrown every obstacle in his way. He afterwards passed into Georgia and Persia, then into Poland, in quality of Pope Urban VIII.'s nuncio, in order to appease the disturbances which had been occasioned there by the disputes of the Armenians, who were very numerous in that country. Piromalli reunited them in the profession of the same faith, and observance of the same ceremonies. In his return to Italy, he was taken by some Corsairs who carried him prisoner to Tunis. As soon as he was ransomed, he went to Rome, and gave an account of his mission to the pope, who conferred upon him some signal marks of his esteem. His holiness intrusted him with the revival of an Armenian Bible, and sent him again into the east, where he was promoted, in 1655, to the bishopric of Nassyvan. After having governed that church for nine years, he returned to Italy, and took the charge of the church of Bassignano, where he died three years after in 1667. His charity, his zeal, and other virtues did honour to the Episcopal office. There are extant of his writings, 1. Some works of Controversy and Theology. 2. Two Dictionaries; the one a Latin-Persian, and the other an Armenian-Latin. 3. An Armenian Grammar. 4. A Directory, which is of great use in correcting Armenian books. All these works equally distinguish him for virtue and for learning.

PIRON (Alexis), whose father was an apothecary, was born at Dijon the 9th of July, 1689 where he passed more than 30 years in the idle and destructive dissipation too common to young men. He was at length obliged to quit the place of his nativity, in order to avoid the reproaches of his fellow-citizens, on account of an ode which he had written, and which gave great offence. His relations not being able to give him much assistance, he supported himself at Paris by means of his pen, the strokes of which were as beautiful and fair as those of an engraver. He lived in the house of M. de Bellisle as his secretary, and afterwards with a financier, who did not know that he had a man of ge-

nins under his roof. His reputation as a writer commenced with some pieces which he published for the entertainment of the populace, and which showed strong marks of original invention, but what fully established his character in this way was his comedy intitled *Métromanie*, which was the best that had appeared in France since Regnard's *Gamelle*. This performance, in five acts, well conducted, replete with genius, wit, and humour, was acted with the greatest success upon the French stage in 1758. The author met with every attention in the capital which was due to a man of real genius, and whose flashes of wit were inexhaustible. We shall insert a few anecdotes of him, which will serve to show his character and turn of mind. In Burgundy the inhabitants of Beaune are called the *Asses of Beaune*. Piron often indulged his satirical disposition at their expence. One day as he was taking a walk in the neighbourhood of that city, he diverted himself with cutting down all the thistles which he met with. When a friend asked him his reason for doing so, he replied, *J'ai à me plaindre des Beaunois; je leur coupe les vivres*, i. e. "I am sorry indeed for the Beaunians; for I am cutting down their food." Being told again that these people would certainly be revenged of him,

Allez, (says he) *Allez; je ne crains point leur impuissant courroux;*

Et, quand je serois seul, je les laisserois tous.

"Get you gone, get you gone: I fear not their feeble revenge; for tho' alone, I should beat them all." Going into a theatre one time where a play was acting, he asked what it was? The Cheats of Scapin, gravely replied a young Beaunian. "Ah! Sir, (says Piron, after thanking him), I took it to be the Cheats of Orestes." In the time of the play, some body addresses the company with "Silence the gentlemen, we dont hear." "It is not at least (cried Piron) for want of ears." A bishop one day asked Piron, during the disputes about Jansenism, "Did you read my mandate, Mr Piron?" "No, my lord; and you—The conversation turning very warm, the bishop reminded him of the distance which birth and rank had put between them. "Sir (says Piron), I have plainly the superiority over you at this moment; for I am in the right and you are in the wrong."—Voltaire's Semiramis did not meet with a very favourable reception the first time it was acted. The author finding Piron behind the scenes asked him what he thought of his performance? "I think (replied he) you would have been pleased that I had been the author it." The performer of the character Ferdinand Cortez (the title of one of Piron's Tragedies) having requested some corrections to be made on the play the first time it was acted, Piron fired at the word *corrections*. The player, who was deputed to wait upon the author with this request, cited the example of Voltaire, who corrected some of his pieces in order to gratify the taste of the public. "The cases are widely different (replied Piron); Voltaire works in chequer work, and I cast in brass." If this answer be not very modest, we must allow that it does not want wit. He thought himself if not superior, at least equal to Voltaire. Some person congratulating him on having composed the best comedy of this age; he answered, with more frankness than modesty, "Add too, and the best tragedy." The following verses are well known, in which he says:

Piron.

Piron.
Pifa.

*En deux mots voulez-vous distinguer & connoître
Le rimour Dijonnais & le Parisien?
Le premier ne fut rien, & ne voulut rien être;
L'autre voulut tout être, & ne fut presque rien.*

We see by these different traits that Piron had a sufficient stock of self conceit. What helped to increase it, and make him fancy himself superior to the most celebrated of his contemporaries, was, that his company, on account of his original humour, of which he had an uncommon share, was more courted than that of Voltaire, who was otherwise too lively, too captious, and crabbed. But those who have favoured us with an account of his many witticisms in conversation, would have done more honour to his memory if they had passed over such as were either indecent or insipid. A thing often pleases over a glass of wine, which will not give the same satisfaction, when it is repeated, especially if in repeating it, you want to make it appear of some importance. Be that as it may, Piron's mischievous ingenuity was partly the cause which excluded him from the French Academy.—“I could not (said he) make thirty-nine people think as I do, and I could still let's think as thirty-nine do.” He called that celebrated society very unjustly *les invalides de l'esprit*, “the invalids of wit;” and yet he often endeavoured to be one of those invalids. His death was hastened by a fall which he got a little before. He died the 21st of January 1773, at the age of 83. He had prepared for himself the following epitaph, in the way of an epigram:

*Ci gît Piron, qui ne fut rien,
Pas même académicien.*

“Here lies Piron, who was nothing, not even an academician”

His wife Maria Theresia Quenandine, who died in 1751, he describes as a sweet and most agreeable companion. They lived together for several years; and no husband ever discharged his duty with more fidelity and attention.

A collection of his works appeared in 1776, in 7 vol. 8vo, and 9 vol. 12mo. The principal pieces are, The School of Fathers; a comedy, acted in 1728 under the title of Ungrateful Sons. Calisthenes; a tragedy, the subject of which is taken from Judin. The Mysterious Lover, a comedy. Gustavus and Ferdinanda Cretz, two tragedies; some scenes of which discover an original genius, but the verification neither pleases the ear nor affects the heart. Metromany, a comedy. The Courses of Tempe, an ingenious pastoral, in which the manners both of the town and country are pleasantly drawn. Some odes, poems, fables, and epigrams. In this last kind of poetry he was very successful, and he may be placed after Marot and Rousseau. There was no occasion for loading the public with 7 vols of his works; the half of that number might have sufficed. For, excepting Metromany, Gustavus, the Courses of Tempe, some odes, about 20 epigrams, three or four fables, and some epistles, the rest are but indifferent, and have no claim to any extraordinary merit.

PISA, a large town of Tuscany in Italy, situated on the river Arno, 52 miles from Florence. It was a famous republic, till subdued, first by the duke of Milan, and then by the Florentines in the year 1406. Before it lost its freedom, it is said to have contained near 150,000 inhabitants, but now it has not above 16,000

or 17,000. It was founded, we are told, by the Pisians of Peloponnesus, and afterward became one of the 12 municipia of Tuscany. Its neighbourhood to Leghorn, which is now the chief port in the Mediterranean, though formerly of little or no note for trade, has contributed greatly to the decay of Pisa, which, however, begins to lift up its head again, under the auspices of the present grand duke, who has made it his winter residence. Between Pisa and Leghorn is a canal 16 Italian miles in length.—Its territory is very fruitful; abounding in corn, wine, and fruit, and fine cattle. The houses are well built, and the streets even, broad, and well paved; but in many places overrun with grass. The university is well endowed, and has able professors, but is not in a very flourishing condition. The exchange is a stately structure, but little frequented. The grand duke's galleys are built and commonly stationed here. This city is also the principal residence of the order of St Stephen, and the see of an archbishop. The cathedral, a large Gothic pile, contains a great number of excellent paintings and other curiosities. This church is dedicated to St Mary; is very advantageously situated in the middle of a large piazza, and built out of a great heap of wrought marble, such as pillars, pedestals, capitals, cornices, and architraves, part of the spoils which the Pisians took in their eastern expeditions, when the republic was in a flourishing condition. The roof is supported by 76 high marble pillars of different colours, and finely gilt. Both the church and the cupola are covered with lead. The choir is painted by good hands, and the floor is mosaic work. The brazen doors are curiously wrought with the history of the Old and New Testament, by Bonanno, an ancient statuary. The chapel of St Rainerius is richly adorned with gilt metals, columns of porphyry, and fine paintings. In the middle of the nave of the church you see two brazen tombs raised upon pillars. The marble pulpit was carved by John Pisano, and the choir by Julian da Majara. Joining thereto is the altar, over which is preserved a hollow globe or vessel of marble, wherein they kept the sacrament for the new baptized, according to the opinion of Father Mabillon. In the square before the church, you see a pillar upon which is the measure of the ancient Roman talent. In the same square with the dome, stands the baptistry, a round fabric supported by stately pillars, and remarkable for a very extraordinary echo.

On the north side of the cathedral is the burying place called *Campo Santo*, being covered with earth, brought from the Holy Land. This burying-place is inclosed with a broad portico well painted, and paved with grave stones. Here are a great many ancient tombs, among the rest that of Beatrix, mother of the countess Mathilda, with marble basso relievos, which the Pisians brought from Greece, where you see the hunt of Meleager, which assisted Nicholas of Pisa in the restoration of sculpture. The walls of the Campo Santo are painted by the best masters of their times. Giotto has drawn six historical pieces of Job; and Andrea Orgagna has given a fine piece of the last judgment. Under the portico there is a decree of the city, ordering the inhabitants to wear mourning a year for the death of Caesar. Near the church you see a steeple in the form of a cylinder, to which you ascend

Pifa.

Pisa
||
Piscidia.

by 153 steps; it inclines 15 feet on one side, which some ascribe to art, but others to the sinking of the foundation. Its inclination is so great that a plumb-line let fall from the top touches the ground at the distance of almost 15 feet from the bottom. It was built by John of Inspruck and Bonanno of Pisa, in 1174. Near this steep is a fine hospital, dependent on that of St Maria Nuova in Florence.

The temple of the church of the Augustinians is also very fine, being an octagon, adorned with pilars, and built by Nicholas of Pisa. In the great market place there is a statue of Plenty, by Pierino da Vinci. In the church of St Matthew, the painting of the ceiling by the brothers Meani, natives of this city, is an admired performance. The church of the knights of St Stephen, decorated with the trophies taken from the Saracens, is all of marble, with marble steps, and a front adorned with marble statues. In the square there is a statue of Cosmo I. upon a very fine pedestal. Contiguous to the church is the convent or palace of the knights, which is worth seeing, as also the churches Della Madonna and Della Spina; the last of which was built by a beggar, whose figure you may see on the outside of the wall. It is pretended that one of the thorns of the crown which was placed on our Saviour's head is preserved here. Belonging to the university there is a great number of colleges, the chief of which is the Sapienza, where the professors read their public lectures; next to which are the colleges Puteano, Ferdinando, Ricci, and others. Besides the public palace, and that of the grand duke, there are several others with marble fronts, the finest of which is that of Lanfranchi, which, with the rest along the banks of the Arno, makes a very fine appearance. There is here a good dock, where they build the galleys, which are conveyed by the Arno to Leghorn. They have a famous aqueduct in this town, consisting of 5000 arches, which conveys the water from the hills at five miles distance. This water is esteemed the best in Italy, and is carried in fasks to Florence and Leghorn. The neighbouring country produces great store of corn and wine, but the latter is not much esteemed. They have very good butter in this neighbourhood, which is a scarce commodity in Italy. The city for its defence has a moat, walls, a castle, fort, and citadel; the last of which is a modern work. The Arno is of a considerable breadth here, and has three bridges over it, one of them of marble; two leagues below the town it falls into the sea. The physic garden is very spacious, contains a great number of plants, and is decorated with water-works: over the door leading into it are these words, *Hic Argus sed non Briareus ossa*: i. e. Employ the Eyes of Argus, but not the hands of Briareus. The air is said to be unwholesome here in summer, on account of the neighbouring morasses. Many buffaloes are bred in the neighbouring country, and their flesh is commonly eaten. Between Pisa and Lucca are hot baths. E. Long. 10. 17. N. Lat. 43. 23.

PISCARY, in the ancient British statutes, the liberty of fishing in another man's waters.

PISCES, in astronomy, the 12th sign or constellation of the zodiac.

PISCIDIA, a genus of the decandria order, belonging to the dialypsia class of plants. There are

two species, viz. 1. The erythrina, or dog wood tree. This grows plentifully in Jamaica, where it rises to the height of 25 feet or more; the stem is almost as large as a man's body, covered with a light-coloured smooth bark, and sending out several branches at the top without order; the leaves are about two inches long, winged, with oval lobes. The flowers are of the butterfly kind, and of a dirty white colour; they are succeeded by oblong pods, with four longitudinal wings, and jointed between the cells which contain the seeds. 2. The Carthaginensis, with oblong oval leaves, is also a native of the West Indies. It differs from the former only in the shape and consistence of the leaves which are more oblong and stiffer; but in other respects they are very similar. Both species are easily propagated by seeds; but require artificial heat to preserve them in Britain.—The negroes in the West Indies make use of the bark of the first species to intoxicate fish. When any number of gentlemen have an inclination to divert themselves with fishing, or more properly speaking, with fish-hunting, they send each of them a negro-slave to the woods, in order to fetch some of the bark of the dog-wood tree. This bark is next morning pounded very small with stones, put into old sacks, carried into rocky parts of the sea, steeped till thoroughly soaked with salt water, and then well squeezed by the negroes to express the juice. This juice immediately colours the sea with a reddish hue; and, being of a poisonous nature, will in an hour's time make the fishes, such as groupers, rock-fish, old wives, Welchmen, &c. so drunk or intoxicated, as to swim on the surface of the water, quite heedless of the danger: the gentlemen then send in their negroes, who pursue, both swimming and diving, the poor inebriated fishes, till they catch them with their hands; their masters in mean time standing by, on high rocks, to see the pastime.

It is remarkable, that though this poison kills millions of the small fry, it has never been known to impart any bad quality to the fish which have been caught in consequence of the intoxication.

The wood of this tree, although pretty hard, is only fit for fuel; and even for this purpose the negroes very seldom, if ever, employ it, on account of its singular quality just mentioned. The bark is rough, brown, and thick; the tree sends forth a considerable number of branches, and is well clothed with leaves which resemble those of the pea, are thick, cottony, and of a deep green. The bark used for the above-mentioned purpose is chiefly that of the roots.

PISCINA, in antiquity, a large basin in a public place or square, where the Roman youth learned to swim; and which was surrounded with a high wall, to prevent filth from being thrown into it.—This word is also used for a lavatory among the Turks, placed in the middle court of a mosque or temple, where the Mussulmen wash themselves before they offer their prayers.

PISISTRATUS, an Athenian who early distinguished himself by his valour in the field, and by his address and eloquence at home. After he had rendered himself the favourite of the populace by his liberality and by the intrepidity with which he had fought their battles, particularly near Salamis, he resolved to make himself master of his country. Every thing seem-

Pisistratus, ed favourable to his ambitious views; but Solon alone, who was then at the head of affairs, and who had lately enforced his celebrated laws, opposed him, and discovered his duplicity and artful behaviour before the public assembly. Pisistratus was not disheartened by the measures of his relation Solon, but he had recourse to artifice. In returning from his country-house, he cut himself in various places; and after he had exposed his mangled body to the eyes of the populace, deplored his misfortunes, and accused his enemies of attempts upon his life, because he was the friend of the people, the guardian of the poor, and the reliever of the oppressed, he claimed a chosen body of 50 men from the populace to defend his person in future from the malevolence and the cruelty of his enemies. The unsuspecting people unanimously granted his request, though Solon opposed it with all his influence; and Pisistratus had no sooner received an armed band on whose fidelity and attachment he could rely, than he seized the citadel of Athens, and made himself absolute. The people too late perceived their credulity; yet though the tyrant was popular, two of the citizens, Megacles, and Lycurgus, conspired together against him, and by their means he was forcibly ejected from the city. His house and all his effects were exposed to sale, but there was found in Athens only one man who would buy them. The private dissensions of the friends of liberty proved favourable to the expelled tyrant; and Megacles, who was jealous of Lycurgus, secretly promised to restore Pisistratus to all his rights and privileges in Athens, if he would marry his daughter. Pisistratus consented; and by the assistance of his father-in-law, he was soon enabled to expel Lycurgus and to re-establish himself. By means of a woman called *Phya*, whose shape was tall, whose features were noble and commanding, he imposed upon the people and created himself adherents even among his enemies. *Phya* was conducted through the streets of the city, and showing herself subservient to the artifice of Pisistratus, she was announced as Minerva, the goddess of wisdom and the patroness of Athens, who was come down from heaven to re-establish her favourite Pisistratus in a power which was sanctioned by the will of Heaven, and favoured by the affection of the people. In the midst of his triumph, however, Pisistratus found himself unsupported; and some time after, when he repudiated the daughter of Megacles, he found that not only the citizens, but even his very troops, were alienated from him by the influence, the intrigues, and the bribery of his father-law-law. He fled from Athens where he no longer could maintain his power, and retired to Eubœa. Eleven years after he was drawn from his obscure retreat, by means of his son Hippias, and he was a third time received by the people of Athens as their master and sovereign. Upon this he sacrificed to his resentment the friends of Megacles, but he did not lose sight of the public good, and while he sought the aggrandizement of his family, he did not neglect the dignity and the honour of the Athenian name. He died about 528 years before the Christian era, after he had enjoyed the sovereign power at Athens for 33 years, and he was succeeded by his son Hipparchus. Pisistratus claims our admiration for his justice, his liberality, and his moderation. If he was dreaded and detested as a tyrant, the Athenians loved and respect-

ed his private virtues and his patriotism as a fellow-citizen; and the opprobrium which generally falls on his head may be attributed not to the severity of his administration, but to the republican principles of the Athenians, who hated and exclaimed against the moderation and equity of the mildest sovereign, while they flattered the pride and gratified the guilty desires of the most tyrannical of their fellow subjects. Pisistratus often refused to punish the insolence of his enemies; and when he had one day been virulently accused of murder, rather than inflict immediate punishment upon the man who had criminated him, he went to the areopagus, and there convinced the Athenians that the accusations of his enemies were groundless, and that his life was irreproachable. It is to his labours that we are indebted for the preservation of the poems of Homer; and he was the first, according to Cicero, who introduced them at Athens in the order in which they now stand. He also established a public library at Athens; and the valuable books which he had diligently collected were carried into Persia when Xerxes made himself master of the capital of Attica. Hipparchus and Hippias the sons of Pisistratus, who have received the name of *Pisistratidæ*, rendered themselves as illustrious as their father; but the flames of liberty were too powerful to be extinguished. The Pisistratidæ governed with great moderation, but the name of tyrant or sovereign was insupportable to the Athenians. Two of the most respectable of the citizens, called *Harmoius* and *Ariflogiton*, conspired against them, and Hipparchus was dispatched in a public assembly. This murder was not, however, attended with any advantages; and though the two leaders of the conspiracy, who have been celebrated through every age for their patriotism, were supported by the people, yet Hippias quelled the tumult by his uncommon firmness and prudence, and for a while preserved that peace in Athens which his father had often been unable to command. This was not long to continue. Hippias was at last expelled by the united efforts of the Athenians and of their allies, and he left Attica, when he found himself unable to maintain his power and independence. The rest of the family of Pisistratus followed him in his banishment; and after they had refused to accept the liberal offers of the princes of Thessaly, and the king of Macedonia, who wished them to settle in their respective territories, the Pisistratidæ retired to Sigæum, which their father had in the summit of his power conquered and bequeathed to his posterity. After the banishment of the Pisistratidæ, the Athenians became more than commonly jealous of their liberty, and often sacrificed the most powerful of their citizens, apprehensive of the influence which popularity and a well-directed liberality might gain among a fickle and unsettled populace. The Pisistratidæ were banished from Athens about 18 years after the death of Pisistratus.

PISMIRES, are a kind of insect very common in Africa; of which there is so great a variety, and such innumerable swarms, that they destroy not only the fruits of the ground but even men and beasts in so little a time as one single night; and would, without all doubt, prove more fatally destructive to the inhabitants were they not so happily destroyed by a proportionable number of monkeys, who greedily ferret and devour them.

Pisistratus,
Pismires.

Piso. them. For a further account of these, and some other grievous plagues with which the far greater part of the vast continent of Africa is afflicted particularly that most horrid visitation of locusts, which seldom fail a year of laying waste some of the provinces, see GRILLUS, p. 161.

PISO (Lucius Calpurnius), surnamed *Frugi* on account of his frugality, was descended of the illustrious family of the Pisces, which gave so many great men to the Roman republic. He was tribune of the people in the year 149 before Christ, and afterwards consul. During his tribuneship, he published a law against the crime of concussion or extortion, intitled *Lex Calpurnia de pecuniis repetundis*. He happily ended the war in Sicily. To reward the services of one of his sons, who had distinguished himself in that expedition, he left him by his will a golden crown, weighing 20 pounds. Piso joined to the qualities of a good citizen the talents of a lawyer, an orator, and historian.

Piso (Caius Calpurnius, a Roman consul in the year 67 before Christ, was author of the law which forbid canvassing for public offices, intitled *Lex Calpurnia de ambitu*. He displayed all the firmness worthy a consul in one of the most stormy periods of the republic. The Roman people, deceived by the flattery of Marcus Palicanus, a turbulent and seditious fellow, were on the eve of loading themselves with the greatest disgrace, by putting the supreme authority into the hands of this man, who deserved punishment rather than honours. The tribunes of the people, by their harangues, inflamed the blind fury of the multitude, already sufficiently mutinous of themselves. In this situation, Piso mounted the rostrum, and being asked if he would declare Palicanus consul in case the suffrages of the people should concur in the nomination, he instantly replied, that "he did not think the republic was yet involved in such darkness and despair as to be capable of committing so infamous an action." Being afterwards strongly and repeatedly called upon to say, "what he would do, if the thing should happen?" his answer was, "No, I would not name him." By this firm and laconic answer he deprived Palicanus of the dignity to which he aspired. Piso, according to Cicero, was not possessed of a quick conception, but he thought maturely, and with judgment, and by a proper firmness, he appeared to be an abler man than he really was.

Piso (Cneius Calpurnius), was consul in the reign of Augustus, and governor of Syria under Tiberius, whose confidant he was. It is said, that by the order of this emperor he caused Germanicus to be poisoned. Being accused of that crime, and seeing himself abandoned by every body, he laid violent hands on himself in the 20th year of our Lord. He was a man of insupportable pride and excessive violence. Some instances of his wicked cruelty have been handed down to us. Having given orders in the heat of his passion to conduct to punishment a soldier, as guilty of the death of one of his companions, because he had gone out of the camp with him and returned without him, no prayers or intreaty could prevail with Piso to suspend the execution of this sentence until the affair should be properly investigated. The soldier was led without the entrenchments, and had already presented his head to receive the fatal stroke, when his compa-

nion whom he was accused of having killed made his appearance again. Whereupon the centurion, whose office it was to see the sentence executed, ordered the executioner to put up his sword into the scabbard. Those two companions, after embracing each other, are conducted to Piso, amidst the acclamations of the whole army, and a prodigious crowd of people. Piso, foaming with rage, ascends his tribune, and pronounces the same sentence of death against the whole three, without excepting the centurion who had brought back the condemned soldier, in these terms; "You I order to be put to death because you have been already condemned; you, because you have been the cause of the condemnation of your comrade; and you, because having got orders to put that soldier to death, you have not obeyed your prince."

PISSASPHALTUM, EARTH-PITCH; a fluid, opaque, mineral body, of a thick consistence, strong smell, readily inflammable, but leaving a residuum of greyish ashes after burning. It arises out of the cracks of the rocks, in several places in the Island of Sumatra, and some other places in the East Indies, where it is much esteemed in paralytic disorders. There is a remarkable mine of it in the island of Bua, (see BUA), of which the following curious description is given us by the Abbé Fortis. "The island is divided into two promontories between the north and west, crossing over the top of the latter, which is not half a mile broad, and descending in a right line towards the sea, one is conducted to a hole well known to the inhabitants. This hole extends not much above 12 feet, and from its bottom above 25 feet perpendicular, arise the marble strata which sustain the irregular masses that surround the top of the mountain.

"The place seemed to me (continues our author), so worthy of observation, that I caused a drawing of it to be taken. The hole AAA is dug out of an irregular stratum of argillaceous sandy earth, in some parts whitish, and in others of a greenish colour; part of it is half petrified, and full of nummules of the largest kind, lenticulares, and fragments, with here and there a small branch of madreporites, and frequently of those other fossil bodies called by Gesner *cornua ammonis candida, minima, &c.* The mass B is fallen from the height of the rock, and lies isolated. The excavation, made by some poor man in the softer matter, reaches a little below the extremity CC of the stratum DD. This is separated by the line EE from the stratum FF, which is of hard common marble, with marine bodies without fints. The upper part *aa* is of hard lenticular stone, interspersed with fints full of lenticulares. The mass H does not discover the divisions of its strata on the outside, and transpires very small drops of pissaspphaltum, scarcely discernible; but the tears III of the same matter, which flow from the fissures and chinks of the whitish stratum DD, are very observable. They come out most abundantly when the sun falls on the marble rock in the heat of the day. This pissaspphaltum is of the most perfect quality, black and shining like the *bitumen Judaicum*; very pure, odorous, and cohesive. It comes out almost liquid, but hardens in large drops when the sun sets. On breaking many of these drops on the spot, I found that almost every one of them had an inner cavity full of very clear water.

Pissaspphaltum.

Plate
cccxcvii.

Pisselæum,
Pistacia. "The greatest breadth of the tears that I saw was two inches, and the common breadth is half an inch. The chinks and fissures of the marble, from whence this bituminous pitch transudes, are not more than the thickness of a thread; and for the most part are so imperceptible, that were it not for the pitch itself, whereby they are blackened, they could not by any means be distinguished by the naked eye. To the narrowness of these passages is, no doubt, in part owing the small quantity of pissasphaltum that transpires."

After some conjectures about the origin of this mine, our author proceeds to inform us that the pissasphaltum of Bua is correspondent to that fossil production which by Hasselquist, in his Travels, is called *mumia minerale*, and *mumia nativa Persiana* by Kestler, which the Egyptians made use of to embalm their kings (A). It is found in a cave of mount Caucasus, which is kept shut, and carefully guarded by order of the king of Persia. One of the qualities assigned by M. Linnæus to the finest bitumen is to smoke when laid on the fire, emitting a smell of pitch not disagreeable. He believes it would be very good for wounds, as the oriental *mumia* is, and like the pitch of Castro, which is frequently used by the Roman surgeons for fractures, contusions, and in many external applications. See MINERALOGY.

PISSELÆUM INDICUM, Barbadocs Tar; a mineral fluid of the nature of the thicker bitumens, and of all others the most approaching, in appearance, colour, and consistence, to the true pissasphaltum, but differing from it in other respects. It is very frequent in many parts of America, where it is found trickling down the sides of mountains in large quantities, and sometimes floating on the surface of the waters. It has been greatly recommended internally in coughs and other disorders of the breast and lungs.

PISTACIA, TURPENTINE-TREE, Pistachia nut and Mastich-tree; a genus of the pentandria order, belonging to the dioecia class of plants. There are nine species; of which the most remarkable are, 1. The terebinthus, or pistachia-tree. This grows naturally in Arabia, Persia, and Syria, whence the nuts are annually brought to Europe. In those countries it grows to the height of 25 or 30 feet: the bark of the stem and old branches is of a dark russet colour, but that of the young branches is of a light brown. These are garnished with winged leaves, composed sometimes of two, at other times of three, pair of lobes, terminated by an odd one: these lobes approach towards an oval shape, and their edges are turned backward; and these, when

Vol. XIV.

bruised, emit a smell similar to that of the shell of the nut. Some of these trees produce male and others female flowers, and some have both male and female on the same tree. The male flowers come out from the sides of the branches in loose bunches or catkins. They have no petals, but five small stamina crowned by large four cornered summits filled with farina; and when this is discharged, the flowers fall off. The female flowers come out in clusters from the sides of the branches: they have 10 petals, but a large oval germen supporting three reflexed styles, and are succeeded by oval nuts. 2. The lentiscus, or common mastich-tree, grows naturally in Portugal, Spain, and Italy. Being an evergreen, it has been preserved in Britain in order to adorn the green-houses. In the countries where it is a native, it rises to the height of 18 or 20 feet, covered with a grey bark on the stem; but the branches, which are very numerous, are covered with a reddish-brown bark, and are garnished with winged leaves, composed of three or four pair of small spear-shaped lobes, without an odd one at the end. 3. The orientalis, or true mastich-tree of the Levant, from which the mastich is gathered, has been confounded by most botanical writers with the lentiscus, or common mastich tree, above described, though there are considerable differences between them. The bark of the tree is brown; the leaves are composed of two or three pair of spear-shaped lobes, terminated by an odd one: the outer lobes are the largest; the others gradually diminish, the innermost being the least. These turn of a brownish colour towards the autumn, when the plants are exposed to the open air; but if they are under glasses, they keep green. The leaves continue all the year, but are not so thick as those of the common sort, nor are the plants so hardy.

Culture. The first species is propagated by its nuts; which should be planted in pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed to bring up the plants: when these appear, they should have a large share of air admitted to them, and by degrees they should be exposed to the open air, which at last they will bear in all seasons, though not without great danger of being destroyed in severe winters. The second sort is commonly propagated by laying down the branches, though it may also be raised from the seed in the manner already directed for the pistachia-nut tree: and in this manner also may the true mastich-tree be raised. But this being more tender than any of the other sorts, requires to be constantly sheltered in winter, and to have a warm situation in summer.

5 F

Pistachia

(4) "Mumiahi, or native Persian mummy. It proceeds from a hard rock in very small quantity. It is a bituminous juice, that transudes from the stony superficies of the hill, resembling in appearance coarse shoemaker's wax, as well in its colour as in its density and ductility. While adherent to the rock it is less solid, but is formed by the warmth of the hands. It is easily united with oil, but repels water; it is quite void of smell, and very like in substance to the Egyptian mummy. When laid on burning coals, it has the smell of sulphur tempered a little with that of naphtha, not disagreeable. There are two kinds of this mummy; the one is valuable for its scarcity and great activity. The native place of the best mummy is far from the access of men, from habitations, and from springs of water, in the province of Daraab. It is found in a narrow cave, not above two fathoms deep, cut like a well out of the mass, at the foot of the ragged mountain Caucasus."—*Kempfer. Amen. Pers.*

This description agrees perfectly with the pissasphaltum or fossil mummy of Bua, differing only in the privation of smell, which it is difficult to imagine is totally wanting in the Persian mummy.

Pistia
Piston.

Pistachia nuts are moderately large, containing a kernel of a pale greenish colour, covered with a reddish skin. They have a pleasant, sweet, unctuous taste, resembling that of almonds; and they abound with a sweet and well-tasted oil, which they yield in great abundance on being pressed after bruising them: they are reckoned amongst the analeptics, and are wholesome and nutritive, and are by some esteemed very proper to be prescribed by way of restoratives, eaten in small quantity, to people emaciated by long illness.

PISTIL, among botanists, the little upright column which is generally found in the centre of every flower. According to the Linnæan system, it is the female part of generation, whose office is to receive and secrete the pollen, and produce the fruit. It consists of three parts, viz. germen, stylus, and stigma. See BOTANY, p. 434, and p. 454, 2d column.

PISTOIA is a city of Italy, in the duchy of Tuscany, situated on the river Stella, in a beautiful plain near the foot of the Apennine mountains. By Pliny it is called *Pistorium*, and is said to have been once a Roman colony. At present it is a bishop's see, suffragan of Florence. The streets are broad and regular, the houses tolerably well built, but poorly inhabited for want of trade. Formerly it was an independent republic, but since it was subdued by the Florentines in 1200, it has been in a declining condition. The cathedral has a very handsome cupola, and a magnificent staircase to ascend to it. In the chapel dedicated to St James, where his relics are preserved, the walls are almost covered with plates of silver. Here are four marble statues of very good workmanship. The marble pulpit, the basso-relievos, the vessel that holds the holy water, and the square steeple, are the work of John Pisano. The Jesuits have a very fine college, and the Franciscans, Dominicans, and Augustinians, good churches. In the church of Madonna dell' Umiltà there are two statues, one of Leo X. and the other of Clement VII. The public palace, situated in a large square, is a handsome building; several of the nobility have also very good houses. In the neighbouring mountains, called by the name of Pistoia, there are many large villages, the chief of which is that of S. Marcello, belonging to the family of Cartoli. These mountains are a part of the Apennines, and border on the territory of Bologna and the county of Vernio; higher up is the source of the river Reno. The country about Pistoia, especially towards Florence, is exceeding fertile and delightful, covered with all sorts of fruits, corn, wine, &c. and containing a vast number of little towns, wealthy villages, and country seats, so as to be reckoned the richest and most beautiful in all Tuscany. It is about 20 miles N. W. of Florence, and 30 N. E. of Pisa. E. Long. 11. 29. N. Lat. 43. 55.

PISTOL, the smallest piece of fire-arms, borne at the saddle bow, on the girdle, and in the pocket.

PISTOLE, a gold coin, struck in Spain and in several parts of Italy, Switzerland, &c.—The pistole has its augmentations and diminutions, which are quadruple pistoles, double pistoles, and half pistoles. See *MONY Table*.

PISTON, in pump-work, is a short cylinder of metal or other solid substance, fitted exactly to the cavity of the barrel or body of the pump. See HYDROSTATICS, sect. v.

PISTORIUS (John), born at Nidda in 1546, applied himself at first to the study of medicine, and was admitted a doctor with applause; but his prescriptions not being attended with all the success which he expected, he quitted that profession, and studied the law. His merit procured him the appointment of counsellor to Ernest Frederick margrave of Bade-Durlach. He had embraced the Protestant religion; but some time after he changed his opinion, and returned to the communion of the church of Rome. He became afterwards a doctor of divinity, one of the emperor's counsellors, provost of the cathedral of Breslaw, and domestic prelate to the abbot of Fulda. We have of his writings, 1. *Several Controversial Tracts* against the Lutherans. 2. *Artis Cabalisticæ Scriptores*, printed at Bale 1587; a scarce and curious collection. 3. *Scriptores rerum Polonicarum*. 4. *Scriptores de rebus Germanicis*, in 3 vols. folio, from 1603 to 1613. This is a curious and scarce performance, but might have been better digested. The author died in 1608, at the age of 52.

PISUM, PEASE; a genus of the decandria order, belonging to the diadelphia class of plants. The species are, 1. The sativum, or greater garden-pea, whose lower stipulæ are roundish, indented, with taper foot-stalks, and many flowers on a foot-stalk. 2. The humile, or dwarf pea, with an erect branching stalk, and leaves having two pair of round lobes. 3. The umbellatum, rose, or crown-pea, with four pointed acute stipuli, and foot-stalks bearing many flowers, which terminate the stalks. 4. The maritimum, or sea-pea, with foot stalks which are plain on their upper side, an angular stalk, arrow-pointed stipulæ, and foot-stalks bearing many flowers. 5. The Americanum, commonly called *Cape Horn pea*, with an angular trailing stalk, whose lower leaves are spear-shaped, sharply indented, and those at the top arrow-pointed. 6. The ochrus, with membranaceous running foot-stalks, having two leaves and one flower upon a foot-stalk.

There is a great variety of garden pease now cultivated in Britain, which are distinguished by the gardeners and seedsmen, and have their different titles; but as great part of these have been feminal variations, so if they are not very carefully managed, by taking away all those plants which have a tendency to alter before the seeds are formed, they will degenerate into their original state: therefore all those persons who are curious in the choice of their seeds, look carefully over those which they design for seeds at the time when they begin to flower, and draw out all the plants which they dislike from the other. This is what they call *roguing their pease*; meaning hereby the taking out all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which, they always do it before the flowers open. By thus diligently drawing out the bad, reserving those which come earliest to flower, they have greatly improved their pease of late years, and are constantly endeavouring to get forwarder varieties; so that it would be to little purpose in this place to attempt giving a particular account of all the varieties now cultivated: therefore we shall only mention the names by which they are commonly known, placing them according to their time of coming to the table, or gathering for use.

Pistorius,
Pisum.

Pisum.	The golden hotspur.	Nonparcil.
	The Charlton.	Sugar dwarf.
	The Reading hotspur.	Sickle pea.
	Master's hotspur.	Marrowfat.
	Essex hotspur.	Rose or crown pea.
	The dwarf pea.	Rouncival pea.
	The fugur pea.	Gray pea.
	Spanish Morotto.	Pig pea; with some others.

The English sea-pea is found wild upon the shore in Suffex and several other countries in England, and is undoubtedly a different species from the common pea.

The fifth species hath a biennial root, which continues two years. This was brought from Cape Horn by Lord Anson's cook, when he passed that Cape, where these pease were a great relief to the sailors. It is kept as a curiosity, but the pease are not so good for eating as the worst sort now cultivated in Britain. It is a low trailing plant; the leaves have two lobes on each foot-stalk: those below are spear-shaped, and sharply indented on their edges; but the upper leaves are small, and arrow pointed. The flowers are blue, each foot-stalk sustaining four or five flowers; the pods are taper, near three inches long; and the seeds are round, about the size of tares.

The sixth sort is annual. This grows naturally among the corn in Sicily and some parts of Italy, but is in England preserved in botanic gardens for the sake of variety. It hath an angular stalk, rising near three feet high; the leaves stand upon winged foot-stalks, each sustaining two oblong lobes. The flowers are of a pale yellow colour, shaped like those of the other sort of pea, but are small, each foot-stalk sustaining one flower; these are succeeded by pods about two inches long, containing five or six roundish seeds, which are a little compressed on their sides. These are by some persons eaten green; but unless they are gathered very young, they are coarse, and at best not so good as the common pea. It may be sown and managed in the same way as the garden pea.

We shall now proceed to set down the method of cultivating the several sorts of garden pease, so as to continue them throughout the season.

It is a common practice with the gardeners near London to raise pease upon hot-beds, to have them very early in the spring; in order to which they sow their pease upon warm borders, under walls or hedges, about the middle of October; and when the plants come up, they draw the earth up gently to their stems with a hoe, the better to protect them from frost. In these places they let them remain until the latter end of January, or the beginning of February, observing to earth them up from time to time as the plants advance in height (for the reasons before given); as also to cover them in very hard frost with pease-haulm, straw, or some other light covering, to preserve them from being destroyed; they then make a hot-bed (in proportion to the quantity of pease intended), which must be made of good hot dung, well prepared and properly mixed together, that the heat may not be too great. The dung should be laid for two or three feet thick, according as the beds are made earlier or later in the season; when the dung is equally levelled, then the earth (which should be light and fresh, but not over rich) must be laid thereon about six or eight inches thick, laying it equally all over the bed. This being done, the frames

(which should be two feet high on the back side, and about 14 inches in front) must be put on, and covered with glasses; after which it should remain for three or four days, to let the steam of the bed pass off before you put the plants therein, observing every day to raise the glasses to give vent for the rising steam to pass off; then, when you find the bed of a moderate temperature for heat, you should, with a trowel, or some other instrument, take up the plants as carefully as possible to preserve the earth to their roots, and plant them into the hot bed in rows about two feet asunder, and the plants about an inch distant from each other in the rows, observing to water and shade them until they have taken root; after which you must be careful to give them air at all times when the season is favourable, otherwise they will draw up very weak, and be subject to grow mouldy and decay. You should also draw the earth up to the flanks of the plants as they advance in height, and keep them always clear from weeds. The water they should have must be given them sparingly; for if they are too much watered, it will cause them to grow too rank, and sometimes rot off the plants at their flanks just above ground. When the weather is very hot, you should cover the glasses with mats in the heat of the day, to screen them from the violence of the heat of the sun, which is then too great for them: but when the plants begin to fruit, they should be watered oftener, and in greater plenty than before; for by that time the plants will have nearly done growing, and the often refreshing them will occasion their producing a greater plenty of fruit.

The sort of pea which is generally used for this purpose is the dwarf; for all the other sorts ramble too much to be kept in frames: the reason for sowing them in the common ground, and afterwards transplanting them on a hot-bed, is to check their growth, and cause them to bear in less compass; for if the seeds were sown upon a hot-bed, and the plants continued thereon, they would produce such luxuriant plants as could not be contained in the frames, and would bear but little fruit.

The next sort of pea which is sown to succeed those on the hot-bed is the hotspur; of which there are reckoned several varieties, as the golden hotspur, the Charlton hotspur, the Master's hotspur, the Reading hotspur, and some others; which are very little differing from each other, except in their early bearing, for which the golden and Charlton hotspurs are chiefly preferred; though if either of these sorts are cultivated in the same place for three or four years, they are apt to degenerate, and be later in fruiting; for which reason, most curious persons procure their seeds annually from some distant place; and in the choice of these seeds, if they could be obtained from a colder situation and a poorer soil than that in which they are to be sown, it will be much better than on the contrary, and they will come earlier in the spring.

These must also be sown on warm borders, towards the latter end of October; and when the plants are come up, you should draw the earth up to their flanks, and treat them in every other respect as above directed.

In the spring you must carefully clear them from weeds, and draw some fresh earth up to their stems; but do not raise it too high up to the plants, lest by burying

Pisum.

burying their leaves you should rot their stems, as is sometimes the case, especially in wet seasons. You should also observe to keep them free from vermin, which, if permitted to remain amongst the plants, will increase so plentifully as to devour the greatest part of them. The chief of the vermin which infest pease are slugs, which lie all the day in the small hollows of the earth, near the stems of the plants, and in the night-time come out and make terrible destruction of the pease; and these chiefly abound in wet soils, or where a garden is neglected and over-run with weeds: therefore you should make the ground clear every way round the pease to destroy their harbours; and afterwards in a fine mild morning very early, when these vermin are got abroad from their holes, you should strew a quantity of lime, which should be strewed over the ground pretty thick, which will destroy the vermin wherever it happens to fall upon them, but will do very little injury to the pease, provided it be not scattered too thick upon them.

If this crop of pease succeeds, it will immediately follow those on the hot-bed; but for fear this should miscarry, it will be proper to sow two more crops at about a fortnight or three weeks distance from each other, so that there may be the more chances to succeed. This will be sufficient till the spring of the year, when you may sow several more crops of these pease at a fortnight distance from each other. The late sowings will be sufficient to continue the early sort of pease through the season; but it will be proper to have some of the large sort to succeed them for the use of the family: in order to which, you should sow some of the Spanish Morotto, which is a great bearer and a hardy sort of pea, about the middle of February, upon a clear open spot of ground. These must be sown in rows about four feet asunder, and the pease should be dropped in the drills about an inch distance, covering them about two inches deep with earth, being very careful that none of them lie uncovered, which will draw the mice, pigeons, or rooks, to attack the whole spot; and it often happens, by this neglect, that a whole plantation is devoured by these creatures; whereas, when there are none of the pease left in sight, they do not easily find them out.

About a fortnight after this you should sow another spot, either of this sort or any other large sort of pea, to succeed these; and then continue to repeat sowing once a fortnight, till the middle or latter end of May; only observing to allow the marrowfats, and other very large sorts of pease, at least four feet and a half between row and row; and the rose-pea should be allowed at least eight or ten inches distance plant from plant in the rows; for these grow very large, and if they have not room allowed them, they will spoil each other by drawing them up very tall, and will produce no fruit.

When the plants come up, the earth should be drawn up to their stanks (as was before directed), and the ground kept entirely clear from weeds; and when the plants are grown eight or ten inches high, you should stick some brushwood into the ground close to the pease for them to ramp upon, which will support them from trailing upon the ground, which is very apt to rot the growing sorts of pease, especially in wet seasons; besides, by thus supporting them, the air can freely pass between them, which will preserve the blossoms from

falling off before their time, and occasion them to bear much better than if permitted to lie upon the ground, and there will be room to pass between the rows to gather the pease when they are ripe.

The dwarf sorts of pease may be sown much closer together than those before-mentioned; for these seldom rise above a foot high, and rarely spread above half a foot in width, so that these need not have more room than two feet row from row, and not above an inch asunder in the rows. These will produce a good quantity of pease, provided the season be not over dry; but they seldom continue long in bearing, so that they are not so proper to sow for the main crop, when a quantity of pease is expected for the table, their chief excellency being for hot-beds, where they will produce a greater quantity of pease (provided they are well-managed) than if exposed to the open air, where the heat of the sun soon dries them up.

The large growing sorts may be cultivated for the common use of the family, because these will produce in greater quantities than the other, and will endure the drought better; but the early kind are by far the sweeter-tasted pease.

The best of all the large kinds is the marrowfat, which, if gathered young, is a well-tasted pea; and this will continue good through the month of August, if planted on a strong soil.

The gray and other large winter-pease are seldom cultivated in gardens, because they require a great deal of room, but are usually sown in fields. For the proper method of managing them, see AGRICULTURE, n^o 150.

In the *Museum Rusticum*, Vol. I. p. 109. we find the following method of preparing pease for hog-meat, which we shall give in the words of the ingenious farmer who communicated it.

“A few years ago (says he), I had a plentiful crop of pease on a ten acre piece, which lies near my house: when they were full podded and nearly ripe, I had them hooked in the usual manner; but before I could get them in, there came a heavy shower of rain which wetted them through and through; and the dull heavy weather, with frequent showers which followed, prevented their drying for a considerable time.

“I caused the wads to be from time to time turned, to prevent the haulm from rotting; and at length a few days sunshine dried them enough to be inned; for as they lay hollow, the wind was greatly assistant to the operation.

“Before I got them in, on examining some of the pods, I found that the pease were all sprouted to a considerable length: this was what I had expected, as I gave my crop over for lost, till after a little recollection, as the weather still continued fine, I determined to thresh them in the field.

“This was accordingly done; and the corn, after it was cast and riddled to separate it from the rubbish, was dried on my malt kiln.

“When this operation was over, I began to reflect in what manner I should dispose of my pease, being sensible that they could not be proper for feed, and standing in no chance of disposing of them to any advantage in the market.

“At length, as it was then a time of war, and of course there was a great demand for pork for the use of the navy, I determined to buy a considerable num-

Pisum.

Pifum,
Pit-coal. ber of lean hogs, that I might by their means consume this crop on my own premises, and in that manner make the most of it.

“ My expectations were more than answered; for I found, by repeated experience, that three bushels of the pease I have mentioned went nearly as far in fattening the hogs I bought as four bushels got in dry and hard in the manner usually practised.

“ This discovery I made several years ago, and it has turned out to my advantage; for since that time I have been quite indifferent as to the weather in which my pease are sown, being rather better pleased, as far as relates to them, with wet than dry weather; but if the weather happens to be dry at the time they are sown, I always cause as many as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the same manner nearly as my barley: this management has of late succeeded very well with me, and I therefore intend to continue it.

“ Besides feeding my hogs with these malted pease, I have often given them to my horses, with which they agree very well, and are heartening food.

“ Turkeys will fatten apace on them also, and be fine meat.

“ I have applied my malted pease to many other uses, which I have not at present time to enumerate: but were they only used for feeding hogs and horses, it is still worth while to prepare some in this manner every year.”

PIT-COAL, or STONE-COAL. See **COAL** and **LITHANTHRAX.**

Mr Bertrand, in his *Oryctologic Dictionary*, reduces all kinds of coals to six general classes, viz. 1. Lithanthrax ligneus; 2. Petrofusus; 3. Terreltris; 4. Piceus; 5. Fossilis; 6. Mineralisatus. He says, that the Scots coals are heavier, and burn not so well as those of Newcastle; that those of Liege burn quicker; and those from Brassac in Auvergne, and from La Fosse, burn with a more agreeable flame, &c. But Mr Morand, in his *Nomenclature Raisonnée*, distributes all sorts of pit-coals into four classes: In the first he places nine varieties, beginning with the *gagas* or *lucinum nigrum*, to the variegated lithanthrax; in the second he reckons seven varieties, beginning with the *lithanthrax eleganti structura*, to that *facie granulata*: and he forms the fourth class with the earthy and poorer kinds of fossil coals. He seems, however, to have been puzzled with the slaty coals, as he ranges them in a separate class, perhaps to shelter himself from the critical objections of those numerous superficial naturalists, who only look for the apparent configuration, without almost any regard to the component parts of fossils.

The coal-trade is of infinite importance to Great Britain, which never could have arrived at its present commercial eminence without it; and this eminence it will be impossible to retain if coal should ever become scarce. This we trust is not likely to be the case, though Mr Williams expresses great fears for it, and informs us that at Newcastle and in many parts of Scotland the mines near the sea are already wasted, the first consequence of which must be an enormous rise in the price. See his observations on this subject in his *Natural History of the Mineral Kingdom*, p. 156, &c. This author says, that coal was not discovered till between the middle of the 12th and beginning of the 13th centuries: it is therefore, according to him, 400 years since it was first

discovered in Britain, but they have not been in common use for more than 200 years. The same author gives us many pertinent observations on the appearances and indications of coal, instructions about searching for it, remarks on false and doubtful symptoms of coal; for all which, together with his observations on the different kinds of Scots coal, we shall refer our readers to the work itself; the first part of which, occupying the largest proportion of the first volume, is upon the *strata of coal*, and on the *concomitant strata*. See also our article **COALERY.**

PITAHAYA (*Cactus Pita'aya*, Lin. *Syst. Vegetabilium*. *Jacquin Amer.* 151. ed. 2. p. 75. M. *B. Carthagena*), a shrub peculiar to California, is a kind of beech, the fruit of which forms the greatest harvest of the natives. Its branches are finely fluted, and rise vertically from the stem, so as to form a very beautiful top. The fruit is like a horse-chestnut. In some white, in others yellow, and in others red, but always exquisitely delicious, being a rich sweet, tempered with a grateful acid. See **CACTUS.**

PITCAIRNE (Dr Archibald), a most eminent physician and ingenious poet, was descended from the ancient family of the Pitcairnes of Pitcairne in Fifeshire, and was born at Edinburgh on the 25th of December 1652. He commenced his studies at the school of Dalkeith; and from thence he was removed to the university of Edinburgh, where he improved himself in classical learning, and completed a regular course of philosophy. His friends, according to the authors of the *Biographia Britannica*, were desirous that he should follow the profession of theology. The unpleasant gloom, however, which at that time hung over religion and its professors in Scotland, could not but very ill suit with that native cheerfulness of temper and liberality of mind which made him, long after, a mark for the arrows of preciseness and grimace. The law seems to have been his own choice, and to this science he turned his attention. With an ardour peculiar to himself, and an ambition to excel in whatever he undertook, he pursued it with so much intenseness, that his health began to be impaired. On this account, his physicians advised him to set out for the south of France. By the time he reached Paris, he was happily so far recovered, that he determined to renew his studies; but being informed that there was no able professor of law in that city, and finding several gentlemen of his acquaintance engaged in the study of physic, he went with them to the lectures and hospitals, and employed himself in this manner for several months till his affairs called him home.

On his return, he applied himself chiefly to the mathematics. It is not usual to see the briars of this science and the flowers of poetry growing in the same soil. Here, however, they were happily united; and to this union perhaps was owing that singular command of judgment, over one of the liveliest of fancies, which appears in every part of his works. His intimacy with Dr David Gregory, the celebrated mathematical professor, began about the same time; and probably conduced to cherish his natural aptitude for this study. It was then, in a great measure, new to him; it soon became his principal delight; his progress in it was rapid, and correspondent to his progress in other pursuits. His improvements on the method of infinite series then adopted, which Dr Wallis of Oxford afterwards

Pitalava,
Pitcairne.

Pitcairne. wards published, were a conspicuous and early proof of his abilities in this science.

Had Dr Pitcairne continued to prosecute the study of the law, and could he have moulded his principles to the times, the first offices and honours of the state might have been looked for without presumption as the probable reward of such talents as he possessed. Struck, however, with the charms of mathematical truth which had been lately introduced into the philosophy of medicine, and hoping to reduce the healing art to geometrical method, he unalterably determined on this less aspiring profession. At the period when he formed this resolution, the ideas of the medical world, already sufficiently confused, were still farther jumbled by the discovery of the circulation of the blood, which had as yet produced nothing but doubt, uncertainty, and astonishment. In Edinburgh at that time there was no school, no hospital, no opportunity of improvement but the chamber and the shop. He therefore soon after returned to Paris. Genius and industry are unhappily not often united in the same character: of such an union, however, Dr Pitcairne is a celebrated instance. During his residence in France, he cultivated the object of his pursuit with his natural enthusiasm, and with a steadiness from which he could not be diverted by the allurements of that joy which, in his hours of social and festive intercourse, he always felt and always gave. Among his various occupations, the study of the ancient physicians seems to have had a principal share. This appears from a treatise which he published some time after his return; and it shows, that he wisely determined to know the progress of medicine from its earliest periods, before he attempted to reform and improve that science.

On the 13th of August 1680, he received, from the faculty of Rheims the degree of Doctor; which, on the 7th of August 1699, was likewise conferred on him by the university of Aberdeen; both being attended with marks of peculiar distinction. Other medical honours are said to have been conferred on him in France and elsewhere; but nothing affords a more unequivocal testimony to his abilities than that which the surgeons of Edinburgh gave, in admitting him, freely and unsolicited, a member of their college. None had such opportunities of judging of his merit as a practitioner, and on no physician did they ever bestow the same public mark of respect. Soon after his graduation at Rheims, he returned to Edinburgh; where, on the 29th of November 1681, the Royal College of Physicians was instituted; and his name, among others, graced the original patent from the crown.

In his *Solutio Problematis de Inventoribus*, the treatise above alluded to, he discovers a wonderful degree of medical literature, and makes use of it in a manner that does great honour both to his head and his heart. His object is to vindicate Dr Harvey's claim to the discovery of the circulation of the blood. The discovery was, at first, controverted by envy, and reprobed by ignorance. When at length its truth

was fully established, many invidiously attempted to tear the laurels from the illustrious Englishman, and to plant them on the brows of Hippocrates and others. Had the attempt been directed against himself, the generous soul of Pitcairne could not have exerted more zeal in a defence; and his arguments remain unanswered.

During his residence in Scotland, his reputation became so considerable, that, in the year 1691, the university of Leyden solicited him to fill the medical chair, at that time vacant. Such an honourable testimony of respect, from a foreign nation, and from such an university, cannot perhaps be produced in the medical biography of Great Britain. The lustre of such characters reflects honour on their profession, and on the country which has the good fortune of giving them birth; and serves to give the individuals of that country not only a useful estimation in their own eyes, but in those also of the rest of the world. Dr Pitcairne's well known political principles excluded him from public honours and promotion at home: he therefore accepted the invitation from abroad; and, on the 26th of April 1692, delivered, at Leyden, his elegant and masterly inaugural oration: *Oratio qua ostenditur medicinam ab omni philosophorum secta esse liberam*. In this he clears medicine from the rubbish of the old philosophy; separates it from the influence of the different sects; places it on the broad and only sure foundation of experience; shows how little good inquiries into the manner how medicines operate have done to the art; and demonstrates the necessity of a sedulous attention to their effects, and to the various appearances of disease.

Nothing (says an elegant panegyrist* of our author) • Dr Charles Webster, in the Harveian Oration at Edinburgh for the year 1781; from which performance the present article is chiefly extracted.

marks a superiority of intellect so much as the courage requisite to stem a torrent of obstinately prevailing and groundless opinions. For this the genius and talents of Pitcairne were admirably adapted; and, in his oration, he displays them to the utmost. It was received with the highest commendations; and the administrators, to testify their sense of such an acquisition to their university, greatly augmented the ordinary appointment of his chair.

He discharged the duties of his office at Leyden so as to answer the most sanguine expectations. He taught with a perspicuity and eloquence which met with universal applause. Independently of the encomiums of Boerhaave and Mead, who were his pupils, the numerous manuscript copies of his lectures, and the mutilated specimen of them† which found its way †Elementæ Medicinæ.

into the world without his knowledge, show how justly it was bestowed. At the same time, he was not more celebrated as a professor than as a practical physician; and notwithstanding the multiplicity of his business in both these characters, he found leisure to publish several treatises on the circulation, and some other of the most important parts of the animal economy (A).

At the close of the session he set out for Scotland, with an intention of returning in time for the succeeding one. On his marrying (B) the daughter of Sir Archibald

(A) Dr Boerhaave gives the following character of these and some other of Dr Pitcairne's dissertations, which were collected and published at Rotterdam, anno 1701: "Hæc scripta optima sunt et perfecta, sive legas Dissertationem de Motu Sanguinis per Pulmones, sive alia opuscula, sive ultimum tractatum de Opio."

Methodus Audii, ab Hallero edita, p. 569.

(B) He had been married before to a daughter of Colonel James Hay of Pitfour, by whom he had a son and daughter, who both died young.

Pitcairne. Archibald Stevenson, the object of his journey, her relations would on no account consent to part with him again. He was therefore reluctantly obliged to remain; and he wrote the university a polite apology, which was received with the utmost regret. He even declined the most flattering solicitations and tempting offers to settle in London. Indeed he soon came into that extensive practice to which his abilities intitled him, and was also appointed titular professor of medicine in the university of Edinburgh.

The uniformity of a professional life is seldom interrupted by incidents worthy of record. Specimens, however, of that brilliant wit with which he delighted his friends in the hours of his leisure, continue to entertain us (c); and the effects of that eminent skill which he exerted in the cure of disease, still operate to the good of posterity.

The discovery of the circulation, while in some measure it exploded the chemical and Galenical doctrines, tended to introduce mathematical and mechanical reasoning in their stead. Of this theory (D) Dr Pitcairne was the principal support, and the first who introduced it into Britain. A mathematical turn of mind, and a wish for mathematical certainty in medicine, biased him in its favour, and he pushed it to its utmost extent. One is at a loss whether most to admire or regret such a waste of talents in propping a

theory which, though subversive of former ones, was to fall before others but a little more satisfactory than itself. Mechanical physicians expected more from geometry than that science could grant. They made it the foundation instead of an auxiliary to their inquiries, and applied it to parts of nature not admitting mathematical calculations. By paying more attention afterwards to the supreme influence of the living principle, the source of all the motions and functions of the body, it was found that these could not be explained by any laws of chemistry or mechanism. They are still, however, involved in obscurity; and notwithstanding the numberless improvements which have taken place in the sciences connected with medicine, will perhaps remain inscrutable while man continues in his present stage of existence.

In a science so slowly progressive as that of medicine, Dr Pitcairne did a great deal. By labouring in vain for truth in one road, he saved many the same drudgery, and thereby showed the necessity of another. He not only exploded many false notions of the chemists and Galenists which prevailed in this time, but many of those too of his own sect. In particular, he showed the absurdity of referring all diseases and their cures to an alkali or an acid (E). He refuted the idea of secretion being performed by pores differently shaped (F), Bellini's opinion of effervescences in the

(c) Vide *Pitcairni Poemata*.—Several of his poems, however, are obscure, and some of them totally unintelligible without a key. In those of them which are of a political kind, he wished not to express himself too clearly; and in others, he alludes to private occurrences which were not known beyond the circle of his companions. His poem (*Ad Lindesum*), addressed to his friend Lindsey, is commented on by the authors of the *Biographia Britannica*; and it is to be regretted that it is the only one on which they have been solicitous to throw light. "Some parts (say they) of this poem, are hardly intelligible, without knowing a circumstance in the Doctor's life, which he often told, and never without some emotion. It is a well known story of the two Platonic philosophers, who promised one another, that whichever died first should make a visit to his surviving companion. This story being read by Mr Lindsey and our author together, they, being both then very young, entered into the same engagement. Soon after, Pitcairne, at his father's house in Fife, dreamed one morning that Lindsey, who was then at Paris, came to him, and told him he was not dead, as was commonly reported, but still alive, and lived in a very agreeable place, to which he could not yet carry him. By the course of the post news came of Lindsey's death, which happened very suddenly the morning of the dream. When this is known, the poem is easily understood, and shines with no common degree of beauty.

"Lyndesi! Stygias jam dudum veste per undas,
 "Stagna que Cocytus non adeunda mihi;
 "Excute paulisper Lethæi vincula somni,
 "Ut feriant animum carmina nostra tuum.
 "Te nobis, te redde tuis, promissa daturus
 "Gaudia; sed proavo sis comitante redux:
 "Namque novos viros mutataque regna videbis,
 "Passaque Teutonicas sceptrâ Britannia manus*.

"He then proceeds to exclaim against the principles and practices which produced this Teutonic violence upon the British sceptre; and concludes with a wish, that Lindsey might bring Rhadamanthus with him to punish them.

"Unus abest scelerum vindex Rhadamanthus; amice,
 "Dii faciant reditus sit comes ille tui!

"Every one sees how much keener an edge is given to the satire upon the revolution, by making it an additional reason for his friend's keeping his promise to return him a visit after his death."

Pitcairne. the animal spirits with the blood, and Borelli's of air entering the blood by respiration (c). He proved the continuity of the arteries and veins (h); and seems to have been the first who showed that the blood flows from a smaller capacity into a larger; that the aorta, with respect to the arterial system, is the apex of a cone (i). In this therefore he may be considered as the latent spring of the discoveries respecting the powers moving the blood. He introduced a simplicity of prescription unknown in pharmacy before his time (k); and such was the state of medicine in his country, that scarcely have the works of any cotemporary or preceding author been thought worthy even of preservation (l). As to the errors of his philosophy, let it be remembered, that no theory has as yet stood to the test of many years in an enlightened period. His own hung very loosely about him (m); and the present generally received practice differs from his very little in reality. He treated inflammatory and hemorrhagic diseases by bleeding, purging, and blistering, as has been done uniformly and solely on the different theories since. His method of administering mercury and the bark is observed at this day; and with respect to febrile, nervous, glandular, and dropical affections, they seem to be as often the opprobriums of the art now as they were then.

Dr Pitcairne was universally considered as the first physician of his time. No one appears ever to have had so much practice in his country, or so many consultations from abroad; and no one, from all accounts, ever practised with greater sagacity and success. The highest thought themselves honoured by his acquaintance, and the lowest were never denied his assistance and advice. The emoluments of his profession must have been great; but his charities are known to have been correspondent. The possession of money he postponed to more liberal objects: he collected one of the finest private libraries in the world; which was purchased, after his death, by the Czar of Muscovy. Notwithstanding the fatigues he underwent in the exercise of his profession, his constitution was naturally delicate. About the beginning of October 1713, he became affected with his last illness; and on the 23d he died, regretted by science as its ornament, by his country as its boast, and by humanity as its friend. He left a son and four daughters: of whom only one of the latter now survives. The present noble family of Kelly are his grandchildren.

Some anonymous publications are attributed to Dr Pitcairne, particularly a treatise *De Legibus Hyfflorie Naturalis*, &c.; but the only ones he thought proper to legitimate are his *Dissertationes Medicæ*, and a short essay *De Salut.*

PITCAITHLY. See **PITKEATHLY.**

PITCH, a tenacious oily substance drawn chiefly from pines and firs, and used in shipping, medicine, and various arts: or it is more properly tar inspissated by boiling it over a slow fire. See **TAR.**

Fossil Pitch. See **PETROLEUM.**

PITCHING, in sea-affairs, may be defined the vertical vibration which the length of a ship makes about her centre of gravity; or the movement by which she plunges her head and after part alternately into the hollow of the sea. This motion may proceed from two causes: the waves which agitate the vessel; and the wind upon the sails, which makes her stoop to every blast thereof. The first absolutely depends upon the agitation of the sea, and is not susceptible of inquiry; and the second is occasioned by the inclination of the masts, and may be submitted to certain established maxims.

When the wind acts upon the sails, the mast yields to its effort, with an inclination which increases in proportion to the length of the mast, to the augmentation of the wind; and to the comparative weight and distribution of the ship's lading.

The repulsion of the water, to the effort of gravity, opposes itself to this inclination, or at least sustains it, by as much as the repulsion exceeds the momentum, or absolute effort of the mast, upon which the wind operates. At the end of each blast, when the wind suspends its action, this repulsion lifts the vessel; and these successive inclinations and repulsions produce the movement of pitching, which is very inconvenient; and, when it is considerable, will greatly retard the course, as well as endanger the mast, and strain the vessel.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees*.

* See **Plant.**

PITHO, (fab. hist.) the goddess of persuasion among the Romans. She was supposed to be the daughter of Mercury and Venus, and was represented with a diadem on her head, to intimate her influence over the hearts of man. One of her arms appeared raised as in the attitude of an orator haranguing in a public assembly; and with the other she holds a thunderbolt and fetters, made with flowers, to signify the powers of reasoning and the attractions of eloquence. A caduceus, as a symbol of persuasion, appears at her feet, with the writings of Demosthenes and Cicero, the two most celebrated among the ancients, who understood how to command the attention of their audience, and to rouse and animate their various passions — A Roman courtizan. She received this name on account of the allurements which her charms possessed, and of her winning expressions.

Pithom,
Pithou.

PITHOM, one of the cities that the children of Israel built for Pharaoh in Egypt (Exod. i. 11.) during the time of their servitude. This is probably the same city with Pathumos mentioned by Herodotus, which he places upon the canal made by the kings Necho and Darius to join the Red sea with the Nile, and by that means with the Mediterranean. We find also in the ancient geographers, that there was an arm of the Nile called *Pathmeticus*, *Phatmicus*, *Phatnicus*, or *Phatniticus*. Bochart says, that Pithom and Raames are about five leagues above the division of the Nile, and beyond this river: but this assertion has no proof from antiquity. This author contents himself with relating what was said of Egypt in his own time. Mariham will have Pithom to be the same as Pelusium or Damietta.

PITHOU or **PITHOUREUS** (Peter), a Frenchman of great literary eminence, was descended from an ancient and noble family in Normandy, and born at Troyes in 1539. His taste for literature appeared very early, and his father cultivated it to the utmost. He first studied at Troyes, and was afterwards sent to Paris, where he became first the scholar, and then the friend, of Turnebus. Having finished his pursuits in languages and the belles lettres, he was removed to Bourges, and placed under Cujacius in order to study civil law. His father was well skilled in this profession, and has left no inconsiderable specimen of his judgment in the advice he gave his son with regard to acquiring a knowledge of it; which was, not to spend his time and pains upon voluminous and barren commentators, but to confine his reading chiefly to original writers. He made so rapid a progress, that at seventeen he was able to speak extempore upon the most difficult questions; and his master was not ashamed to own, that even himself had learned some things of him. Cujacius afterwards removed to Valence; and Pithæus followed him, and continued to profit by his lectures till the year 1560. He then returned to Paris, and frequented the bar of the parliament there, in order to join practical forms and usages to his theoretic knowledge.

In 1563, being then 24, he published *Adversaria Subjunctiva*, a work highly applauded by Turnebus, Lipsius, and other learned men; and which laid the foundation of that great and extensive fame he afterwards acquired. Soon after this, Henry III. advanced him to some considerable posts; in which, as well as at the bar, he acquitted himself most honourably. Pithæus being a Protestant, it was next to a miracle that he was not involved in the terrible massacre of St Bartholomew in 1572; for he was at Paris where it was committed, and in the same lodgings with several Huguenots, who were all killed. It seems indeed to have frightened him out of his religion; which having, according to the custom of converts, examined and found to be erroneous, he soon abjured, and openly embraced the Catholic faith. He afterwards attended the duke of Montmorency into England; and on his return, from his great wisdom, good nature, and amiable manners, he became a kind of oracle to his countrymen, and even to foreigners, who consulted him on all important occasions: an instance of which we have in Ferdinand the Grand Duke of Tuscany, who not only consulted him, but even submitted to his determination in a point contrary to his interests. Henry

Vol. XIV.

III. and IV. were greatly obliged to him for combating the League in the most intrepid manner, and for many other services, in which he had recourse to his pen as well as to other means.

Pithæus died upon his birth-day in 1596, leaving behind him a wife whom he had married in 1579, and some children. Thuanus says he was the most excellent and accomplished man of the age in which he lived; and all the learned have agreed to speak well of him. He collected a very valuable library, containing a variety of rare manuscripts, as well as printed books; and he took many precautions to hinder its being dispersed after his death, but in vain. He published a great number of works upon law, history, and classical literature; and he gave several new and correct editions of ancient writers. He was the first who made the world acquainted with the Fables of Phædrus: which, together with the name of their author, were utterly unknown and unheard of, till published from a manuscript of his.

PITISCUS (Samuel), a learned antiquary, born at Zutphen, was rector of the college of that city, and afterwards of St Jerome at Utrecht, where he died on the first of February 1717, aged 90. He wrote, 1. *Lexicon Antiquatum Romanorum*, in two volumes folio; a work which is esteemed. 2. Editions of many Latin authors, with notes; and other works.

PITKEATHLY, or **PITCAITHLY**, is the name of an estate in Strathern in Scotland, famous for a mineral spring. An intelligent traveller * gives the following account of it. "The situation of the mineral spring at Pitcaithly, the efficacy with which its waters are said to operate in the cure of the diseases for which they are used, and the accommodations which the neighbourhood affords, are all of a nature to invite equally the sick and the healthy. Two or three houses are kept in the style of hotels for the reception of strangers. There is no long-room at the well; but there are pleasing walks through the adjoining fields. Good roads afford easy access to all the circumjacent country. This delightful tract of Lower Strathern is filled with houses and gardens, and stations from which wide and delightful prospects may be enjoyed; all of which offer agreeable points to which the company at the well may direct their forenoon excursions; conversation, music, dances, whist, and that best friend to elegant, lively, and social converse, the tea-table, are sufficient to prevent the afternoons from becoming languid: and in the evenings nothing can be so delightful as a walk when the setting sun sheds a soft slanting light, and the dew has just not begun to moisten the grass.—Thus is Pitcaithly truly a rural watering-place. The company cannot be at any one time more in number than two or three families. The amusements of the place are simply such as a single family might enjoy in an agreeable situation in the country; only the society is more diversified by the continual change and fluctuation of the company." See *MINERAL WATERS*, p. 55.

PITOT (Henry), of a noble family in Languedoc, was born at Aramont in the diocese of Uzes, on the 29th of May 1695, and died there on the 27th of December 1771, aged 76. He learned the mathematics without a master, and went to Paris in 1718, where he formed a close friendship with the illustrious

Pitot,
Pitot.

Reaumur. In 1724, he was admitted a member of the Royal Academy of Sciences at Paris, and in a few years rose to the degree of pensioner. Besides a vast number of Memoirs printed in the collection of that society, he published in 1731 the Theory of the Working of Ships, in one volume 4to; a work of considerable merit, which was translated into English, and made the author be admitted into the Royal Society of London. In 1740, the states general of Languedoc made choice of him for their chief engineer, and gave him at the same time the appointment of inspector general of the canal which unites the two seas. That province is indebted to him for several monuments of his genius, which will transmit his name with lustre to posterity. The city of Montpellier being in want of water, Pitot brought from the distance of three leagues two springs which furnish a plentiful supply of that necessary article. They are brought to the magnificent Place du Peyron, and thence are distributed through the city. This astonishing work is the admiration of all strangers. The illustrious marshal de Saxe was the great patron and friend of Pitot, who had taught this hero the mathematics. In 1754 he was honoured with the order of St Michael. In 1735 he had married Maria-Leonina Pharambier de Sabbaloua, descended of a very ancient noble family of Navarre. By this marriage he had only one son, who was first advocate-general of the Court of Accounts, Aids, and Finances of Montpellier. Pitot was a practical philosopher, and a man of uncommon probity and candour. He was also a member of the Royal Society of Sciences of Montpellier; and his eulogium was pronounced in 1772 by M. de Rute perpetual secretary, in presence of the states of Languedoc; as it likewise was at the Royal Academy of Sciences of Paris by Abbé de Fouché, who was then secretary.

PITS (John), the biographer, was born in 1560, at Aulton in Hampshire, and educated at Wykeham's school, near Winchester, till he was about 18 years of age; when he was sent to New-college in Oxford, and admitted probationer fellow. Having continued in that university not quite two years, he left the kingdom as a voluntary Romish exile, and retired to Douay; thence he went to the English college at Rheims, where he remained about a year; and then proceeded to Rom., where he continued a member of the English college near seven years, and was made a priest. In 1589 he returned to Rheims; and there, during two years, taught rhetoric and the Greek language. He now quitted Rheims on account of the civil war in France; and retired to Pont à Mousson in Lorraine, where he took the degrees of master of arts and bachelor in divinity. Hence he travelled into Germany, and resided a year and a half at Triers, where he commenced licentiate in his faculty. From Triers he visited several of the principal cities in Germany; and continuing three years an Ingoldstadt in Bavaria, took the degree of doctor in divinity. Thence having made the tour of Italy, he returned once more to Lorraine; where he was patronised by the cardinal of that duchy, who preferred him to a canonry of Verdun; and about two years after he became confessor to the duchess of Cleves, daughter to the duke of Lorraine. During the leisure he enjoyed in this employment, he wrote in Latin the lives of the kings,

bishops, apostolical men, and writers of England. The last of these, commonly known and quoted by this title, *De illustribus Angliæ scriptoribus*, was published after his death. The three first remain still in manuscript among the archives of the collegiate church of Liverdon. The duke of Cleves dying after Pits had been about twelve years confessor to the duchess, she returned to Lorraine, attended by our author, who was promoted to the deanery of Liverdon, which, with a canonry and officialship, he enjoyed to the end of his life. He died in 1616, and was buried in the collegiate church. Pits was undoubtedly a scholar, and not an inelegant writer; but he is justly accused of ingratitude to Bale, from whom he borrowed his materials, without acknowledgment. He quotes Leland with great familiarity, without ever having seen his book: his errors are innumerable, and his partiality to the Romish writers most obvious; nevertheless we are obliged to him for his account of several popish authors, who lived abroad at the beginning of the Reformation.

PITT (Christopher), an eminent English poet, celebrated for his excellent translation of Virgil's *Æneid*, was born in the year 1699. Having studied four years at New-college, Oxford, he was presented to the living of Pimperne in Dorsetshire, which he held during the remainder of his life. He had so poetical a turn, that while he was a school-boy he wrote two large folios of manuscript poems, one of which contained an entire translation of Lucan. He was much esteemed while at the university; particularly by the celebrated Dr Young, who used familiarly to call him his *son*. Next to his fine translation of Virgil, Mr Pitt gained the greatest reputation by his excellent English translation of Vida's art of poetry. This amiable poet died in the year 1648, without leaving, it is said, one enemy behind him.

PITT (William) earl of Chatham, a most celebrated British statesman and patriot, was born in November 1708. He was the youngest son of Robert Pitt, Esq; of Bocomnock in Cornwall; and grandson of Thomas Pitt, Esq; governor of Fort St George in the East Indies, in the reign of queen Anne, who sold an extraordinary fine diamond to the king of France for 135,000*l.* and thus obtained the name of *Diamond Pitt*. His intellectual faculties and powers of elocution very soon made a distinguished appearance; but at the age of 16 he felt the attacks of an hereditary and incurable gout, by which he was tormented at times during the rest of his life.

His lordship entered early into the army, and served in a regiment of dragoons. Through the interest of the duchess of Marlborough he obtained a seat in parliament before he was 21 years of age. His first appearance in the house was as representative of the borough of Old Sarum, in the ninth parliament of Great Britain. In the 10th he represented Seaford, Aldborough in the 11th, and the city of Bath in the 12th; where he continued till he was called up to the house of peers in 1766. The intention of the duchess in bringing him thus early into parliament was to oppose Sir Robert Walpole, whom he kept in awe by the force of his eloquence. At her death the duchess left him 10,000*l.* on condition, as was then reported, that he never should receive a place in administration.

However,

Pit.

Pitt. However, if any such condition was made, it certainly was not kept on his lordship's part. In 1746 he was appointed vice-treasurer of Ireland, and soon after paymaster general of the forces, and sworn a privy-counsellor. He discharged the office of paymaster with such honour and inflexible integrity, refusing even many of the perquisites of his office, that his bitterest enemies could lay nothing to his charge, and he soon became the darling of the people. In 1755 he resigned the office of paymaster, on seeing Mr Fox preferred to him. The people were alarmed at this resignation; and being disgusted with the unsuccessful beginning of the war, complained so loudly, that, on the 4th of December 1756, Mr Pitt was appointed secretary of state in the room of Mr Fox afterwards Lord Holland; and other promotions were made in order to second his plans. He then took such measures as were necessary for the honour and interest of the nation; but in the month of February 1757, having refused to assent to the carrying on a war in Germany for the sake of his majesty's dominions on the continent, he was deprived of the seals on the 5th of April following. Upon this the complaints of the people again became so violent, that on the 29th of June he was again appointed secretary, and his friends filled other important offices. The success with which the war was now conducted is universally known; yet on the 5th of October 1761, Mr Pitt, to the astonishment of almost the whole kingdom, resigned the seals into his majesty's own hands. The reason of this was, that Mr Pitt, having received certain intelligence that the family-compact was signed between France and Spain, and that the latter was about to join France against them, thought it necessary to prevent her by commencing hostilities first. Having communicated this opinion in the privy council, the other ministers urged that they would think twice before they declared war against that kingdom. "I will not give them leave to think (replied Mr Pitt); this is the time, let us crush the whole house of Bourbon. But if the members of this board are of a different opinion, this is the last time I shall ever mix in its councils. I was called into the ministry by the voice of the people, and to them I hold myself answerable for my conduct. I am to thank the ministers of the late king for their support; I have served my country with success; but I will not be responsible for the conduct of the war any longer than while I have the direction of it." To this bold declaration, the lord who then presided in council made the following reply. "I find the gentleman is determined to leave us; nor can I say that I am sorry for it, since he would otherwise have certainly compelled us to leave him. But if he is resolved to assume the right of advising his majesty, and directing the operations of the war, to what purpose are we called to this council? When he talks of being responsible to the people, he talks the language of the house of commons, and forgets that at this board he is responsible only to the king. However, though he may possibly have convinced himself of his infallibility, still it remains that we should be equally convinced before we can resign our understandings to his direction, or join with him in the measure he proposes."

This conversation, which was followed by Mr Pitt's resignation, is sufficient to show the haughtiness and

impetuous temper of this minister. If, however, these very qualities were sometimes productive of great and good consequences, as appears from the following anecdote. — Preparatory to one of the secret expeditions during the war which ended in 1763 the minister had given orders to the different presiding officers in the military, navy, and ordnance departments, to prepare a large body of forces, a certain number of ships, and a proportionable quantity of stores, &c. and to have them all ready against a certain day. To these orders he received an answer from each of the officers, declaring the total impossibility of a compliance with them. Notwithstanding it was then at a very late hour, he sent immediately for his secretary; and after expressing his resentment at the ignorance or negligence of his majesty's servants, he gave the following commands: — "I desire, Mr Wood, that you will immediately go to Lord Anson; you need not trouble yourself to search the admiralty, he is not to be found there; you must pursue him to the gaming house, and tell him from me, that if he does not obey the orders of government which he has received at my hands, that I will most assuredly impeach him. Proceed from him to Lord Ligonier; and though he should be bolstered with harlots, undraw his curtains, and repeat the same message. Then direct your course to Sir Charles Frederick, and assure him, that if his majesty's orders are not obeyed, they shall be the last which he shall receive from me." In consequence of these commands, Mr Wood proceeded to White's, and told his errand to the first lord of the admiralty; who insisted that the secretary of state was out of his senses, and it was impossible to comply with his wishes: "however, (added he), as madmen must be answered, tell him that I will do my utmost to satisfy him." From thence he went to the commander in chief of the forces, and delivered the same message. He also said that it was an impossible business; "and the secretary knows it, (added the old lord): nevertheless, he is in the right to make us do what we can; and what is possible to do, inform him, shall be done." The surveyor general of the ordnance was next informed of Mr Pitt's resolution; and, after some little consideration, he began to think that the orders might be complied with in the time prescribed. The consequence at last was, that every thing, in spite of impossibilities themselves, was ready at the time appointed.

After his resignation in 1761, Mr Pitt never had any share in administration. He received a pension of 3000*l.* a year, to be continued after his decease, during the survivorship of his lady and son; and this gratuity was dignified with the title of *Baroness of Chatham* to his lady, and that of *Baron* to her heirs male. Mr Pitt at that time declined a title of nobility; but in 1766 accepted of a peerage under the title of *Baron Fishburn and Earl of Chatham*, and at the same time he was appointed lord privy-seal.

This acceptance of a peerage proved very prejudicial to his lordship's character. However, he continued steadfast in his opposition to the measures of administration. His last appearance in the House of Lords was on the 2d of April 1778. He was then very ill and much debilitated; but the question was important, being a motion of the duke of Richmond to address his majesty to remove the ministers, and make peace with America on any terms. His lord-

fit. ship made a long speech, which had certainly overcome his spirits: for, attempting to rise a second time, he fell down in a convulsive fit; and though he recovered for that time, his disorder continued to increase till the 10th of May, when he died at his seat at Hayes. His death was lamented as a national loss. As soon as the news reached the house of commons, which was then sitting, Colonel Bauré made a motion, that an address should be presented to his majesty, requesting that the Earl of Chatham should be buried at the public expence. But Mr Rigby having proposed the erecting of a statue to his memory, as more likely to perpetuate the sense of his great merits entertained by the public, this was unanimously carried. A bill was soon after passed, by which 4000 l. a-year was settled upon John, now earl of Chatham, and the heirs of the late earl to whom that title may descend.—His lordship was married in 1754 to Lady Hester, sister to the earl of Temple; by whom he had three sons and two daughters.

Never perhaps was any life so multifarious as that of Lord Chatham; never did any comprise such a number of interesting situations. To bring the scattered features of such a character into one point of view, is an arduous task. The author of the history of his life* has attempted to do it; and with the outline, of what he has laid in summing up his character, we shall finish our biographical sketch of this wonderful man.

“One of the first things that strikes us, in the recollection of Chatham’s life, is the superior figure he makes among his contemporaries. Men of genius and attraction, a Carteret, a Townshend, and I had almost said a Ha. shield, however pleasing in a limited view, appear evidently in this comparison to shrink into narrower dimensions, and walk a humbler circle. All that deserves to arrest the attention, in taking a general survey of the age in which he lived, is comprised in the history of Chatham. No character ever bore the more undoubted stamp of originality. Unresembled and himself, he was not born to accommodate to the genius of his age. While all around him were depressed by the unbecomely of fashion, or the contagion of vanity, he stood aloof. He consulted no judgment but his own; and he aded from the untainted dictates of a comprehensive soul.

“The native royalty of his mind is eminently conspicuous. He felt himself born to command; and the true king of Britain implicitly obeyed him. In him was realised the fable of Orpheus; and his genius, his spirit, his eloquence, led millions in his train, subdued the rugged savage, and disarmed the range of malignity and envy. Nothing is in its nature so inconsistent as the breath of popular applause; and yet that breath was ever ready: his dash; the greater part of his life. Vanity of success could not divert it; inconsistency of conduct could not change its tenor. The astonishing extent of his views, and the mysterious comprehension of his plans, did not in one respect set him above little things: nothing that was necessary to the execution of his designs was beneath him. In another respect, however, he was infinitely elbanged to little things: followed up in the business of his country, he did not think of the derangement of his own private affairs; for, though indispensed to all the mores of dissipated expence, his affairs, even when his circumstances were

much improved, were always deranged. But the features that seem most eminently to have characterised him, were spirit and intrepidity: they are conspicuous in every action and in every turn of his life; nor did this spirit and intrepidity leave him even at the last.

“The manners of lord Chatham were easy and bland, his conversation was spirited and gay, and he readily adapted himself to the complexion of those with whom he associated. That artificial reserve, which is the never-failing refuge of self-diffidence and cowardice, was not made for him. He was unconstrained as artless infancy, and generous as the noon-day sun: yet had he something impenetrable that hung about him. By an irresistible energy of soul, he was haughty and imperious. He was incapable of associating councils, and he was not formed for the fuxated bands of society. He was a pleasing companion, but an unpliant friend.

“The ambition of our hero, however generous in its aim, was the source of repeated errors in his conduct. To the resignation of lord Carteret, and again, from the commencement of the year 1770, his proceedings were bold and uniform. In the intermediate period they were marked with a verfatity, incident only in general to the most flexible minds. We may occasionally trace in them the indecision of a candidate, and the suppleness of a courtier. In a word, he aimed at the impossible task of flattering at once the prejudices of a monarch, and pursuing unremittedly the interests of the people.

“A feature, too, sufficiently prominent in his character, was vanity, or perhaps pride and conscious superiority. He dealt surely somewhat too freely with invective. He did not pretend to an ignorance of his talents, or to manage the display of his important services. Himself was too often the hero of his tale; and the successes of the last war the burden of his song †.

“Patriotism was also the source of some of his imperfections. He loved his country too well; or, if that may sound absurd, the benevolence at least, that embraces the species, had not sufficient scope in his mind. He once styled himself a *Lover of honourable war*; and in so doing he let us into one trait of his character. The friend of human kind will be an enemy to all war. He indulged too much a puerile antipathy to the house of Bourbon: and it was surely the want of expansive affections that led him to so unqualified a condemnation of American independency.

“But the eloquence of lord Chatham was one of his most striking characteristics. He far outstripped his competitors, and stood alone the rival of antiquity.

“His eloquence was of every kind. No man excelled him in close argument and methodical deduction: but this was not the style into which he naturally fell. His oratory was unlaboured and spontaneous: he rushed at once upon the subject; and usually illustrated it rather by glowing language and original conception, than by cool reasoning. His person was tall and dignified; his face was the face of an eagle; his piercing eye withered the nerves, and looked through the souls of his opponents; his countenance was stern, and the voice of thunder set upon his lips: anon, however, he could descend to the easy and the playful. His voice seemed scarcely more adapted to energy and to terror,

than

* History of the Life of William Pitt, Earl of Chatham.

Pitt.

† Ending in 1763.

Pittacus. than it did to the melodious, the insinuating, and the sportive. If, however, in the enthusiasm of admiration, we can find room for the frigidity of criticism, his action seemed the most open to objection. It was forcible, uniform, and ungraceful. In a word, the most celebrated orators of antiquity were in a great measure the children of labour and cultivation. Lord Chatham was always natural and himself."

To the misfortune of the republic of letters, and of posterity, his lordship never fought the prels. Lord Chesterfield says, "that he had a most happy turn for poetry: but it is more than probable that Chesterfield was deceived; for we are told by his biographer that his verses to Garrick were very meagre, and Lord Chatham himself said that he seldom indulged and seldom avowed it. It should seem, then, that he himself set no great value upon it. Perhaps a proper confidence in one's self is essential to all extraordinary merit. Why should we ambitiously ascribe to one mind every species of human excellence? But though he was no poet, it is more than probable, that he would have excelled as much in writing prose as he did in speaking it.

PITTACUS, a native of Mitylene in Lesbos, was one of the seven wise men of Greece: his father's name was Hyrradius. With the assistance of the sons of Alceus, he delivered his country from the oppression of the tyrant Melanchrus; and in the war which the Athenians waged against Lesbos, he appeared at the head of his countrymen, and challenged to single combat Phrynon the enemy's general. As the event of the war seemed to depend upon this combat, Pittacus had recourse to artifice; and when he engaged, he entangled his adversary in a net which he had concealed under his shield, and easily dispatched him. He was amply rewarded for this victory; and his countrymen, sensible of his merit, unanimously appointed him governor of their city with unlimited authority. In this capacity Pittacus behaved with great moderation and prudence: and after he had governed his fellow-citizens with the strictest justice, and after he had established and enforced the most salutary laws, he voluntarily resigned the sovereign power after having enjoyed it for 10 years, observing that the virtues and innocence of private life were incompatible with the power and influence of a sovereign. His disinterestedness gained him many admirers; and when the Mityleneans wished to reward his public services by presenting him with an immense tract of territory, he refused to accept more land than what should be contained in the distance to which he could throw a javelin. He died in the 70th year of his age, about 579 years before Christ, after he had spent the last 10 years of his life in literary ease and peaceful retirement.

The following maxims and precepts are ascribed to Pittacus: The first office of prudence is to foresee threatening misfortunes, and prevent them. Power discovers the man. Never talk of your schemes before they are executed; lest, if you fail to accomplish them, you be exposed to the double mortification of disappointment and ridicule. Whatever you do, do it well. Do not that to your neighbour which you would take ill from him. Be watchful for opportunities.

Many of his maxims were inscribed on the walls of Apollo's temple at Delphi, to show to the world how

great an opinion the Mityleneans entertained of his abilities as a philosopher, a moralist, and a man. By one of his laws, every fault committed by a man when intoxicated deserved double punishment.

PITTENWEEN, a small town situated on the Frith of Forth, towards the eastern extremity of the county of Tife in North Britain. It takes its name from a small cave in the middle of it anciently called a *swan*, and is remarkable for nothing but the ruins of a religious house, which is sometimes called an *abbey* and sometimes a *preb.* Which of these is the proper denomination it is hardly worth while to inquire; but it appears from the arms of the monastery, still preserved over the principal gate, that the superior, by whatever title he was called, had the privilege of wearing a mitre. This edifice, which seems never to have been large, was, with other monuments of mistaken piety, alienated from the church at the Reformation; and what parts of it now remain adapted to very different uses. Some of the cells of the monks furnish habitations tolerably convenient for the servants of him who, in the careless charge of property, has got possession of the lands which formerly belonged to them. That which seems to have been the gentry is a decent parish church. The porch of the chapel, the only part of that building which exists, has been alternately employed as a stable and a slaughter-house; and the meat killed there has been commonly exposed to sale in the lower part of the steeple of that edifice which is now dedicated to the offices of parochial devotion. Had the moralizing traveller, * Johnstone,

who composed the beautiful and pathetic meditation on the ruins of *Iona*, condescended to visit Pittenween, he would not have viewed the abbey without emotion. Insignificant as the place at present is, it seems to have been of some consequence in the last century: and we are led to infer, from the following extracts from the records, that the inhabitants were opulent, and that the town was fortified.

"Pittenween, decimo-quarto Feb. 1651. The bailies and council being convened, and having received information that his majesty is to be in progress with his court along the coast to-morrow, and to stay at Anstruther house that night, have thought it expedient, according to their bounden duty, with all reverence and due respect, and with all the same solemnity they can, to wait upon his majesty, as he comes through this his majesty's burgh, and make his majesty to eat and drink as he passes; and for that effect hath ordained, that the morn' afternoon the town's colours be put upon the belfere of the steeple, and that at three o'clock the bells begin to ring, and ring on still till his majesty comes hither, and passes to Anstruther: And likewise, that the minister be spoken for, to be with the bailies and council, who are to be in their best apparel, and with them a guard of 24 of the ablest men, with pikes, and other 24 with muskets, all in their best apparel, William Sutherland commanding as captain of the guard; and to wait upon his majesty, and to receive his highness at the West Port, bringing his majesty and court through the town, until they come to Robert Smith's yeet, where an table is to be covered with my Lord's † best carpet; and that George † The West

Pittosporum
Pityocampasis.

with sugar, cannell, and other spices firing; and that James Richardson and Walter Airth have care to have ready eight or ten gallons of good strong ale, with Cantry, sack, Rhenish wine, white and charet wines, that his majesty and his court may eat and drink; and that in the mean time, when his majesty is present, the guard do diligently attend about the court; and so soon as his majesty is to go away, that a sign be made to Andrew Tod, who is appointed to attend the colours on the Replee head, to the effect he may give sign to those who attend the cannon of his majesty's departure, and then the *King's* *ye* *his* *cannons* *to* *be* *off* *shot* *at* *once*. It is also thought fitting, that the minister, and James Richardson the eldest bailie, when his majesty comes to the table, show the great joy and sense this burgh has of his majesty's condescendance to visit the same, with some other expressions of loyalty. All which was acted." N. Lat. 56. 11. W. Long. 2. 49.

PITTOSPORUM, in botany; a genus of the monogynia order, belonging to the pentandria class of plants. The calyx is pentaphyllous; inferior and deciduous. The petals are five in number; the style thread shaped; the capsule somewhat angular, trilobular, and contains three or four angulated seeds, adhering to the capsule by means of a liquid resin in the loculaments. Of this there are three species, *viz.* 1. *Tenuifolium*. 2. *Umbellatum*. 3. *Ceriseum*. The first and second are natives of the Cape of Good Hope; the third grows in Madeira, and flowers in May and June.

PITUITARY GLAND. See ANATOMY, p. 758.

PITYOCAMPASIS, in entomology, the caterpillar of the pine-tree, received its compound name from that substance. It was considered as a poison, and as a remedy, according to its different employment; but our chief information is derived from M. Reaumur, who has attentively observed its manner of life. The animal cannot bear much cold, and is therefore never found in the higher latitudes. It is styled processionary, because it never leaves its hold, where many families reside, till the evening when it feeds in trains, led on by two or three, and this train leaves a ribbon of silk in its way for those behind follow exactly the steps of those which preceded, and each leaves its fibre of silk. Their nests are found in autumn; they are born the middle of September, become torpid in December, and recover their strength again in spring. They then descend from the trees, plunge into the earth, and undergo their last change. It is the *bombix pityocampa* of Fabricius, (*Met. et Hist. Insector.* tom. ii. p. 114. n° 66.), and greatly resembles the processionary caterpillar of the oak. The ancients used it as a vesicatory, and the acrimony seems to reside chiefly in a dust which is concealed in receptacles on its back. This is its offensive weapon, for it is thrown out at will, and produces very troublesome cuts, though the hair of the animal and every part of its body seem to have a similar, but weaker power. The secret is still weaker in winter; but this may depend on the diminished vitality of the human body, as well as on the torpid state of the insect. Their silk is not sufficiently strong for the loom, and in hot water melts almost to a paste. In the earth it forms nests of brown silk, but it is then found with difficulty: in Foxes its silk is extremely tender. Adding to all these inconveniences, handling the cones produces all the bad effects of the dust. Matthioli recommends them

as a styptic, and perhaps they may serve for burning on the skin instead of moxa, the downy silk of a species of artemisia. The ancients, afraid of its hurtful qualities, used them with caution, and enacted laws against their being sold promiscuously: the modern planter is chiefly afraid of them because they destroy the beauty of his trees, and he endeavours to collect the eggs by cutting off the branches, which are burnt immediately.

PIVAT, or PIVOT, a foot or shoe of iron or other metal, usually conical or terminating in a point, whereby a body, intended to turn round, bears on another fixed at rest, and performs its revolutions. The pivot usually bears or turns round in a hole, or piece of iron or brass hollowed to receive it.

PIUS II. (*Æneas-Sylvius Piccolomini*), was born on the 18th of October 1405 at Corsigni in Siense, the name of which he afterwards changed into that of *Pienza*. His mother *Victoria Forteguerra*, when she was with child of him, dreamed that she should be delivered of a mitred infant; and as the way of degrading clergymen at that time was by crowning them with a paper mitre, she believed that *Æneas* would be a disgrace to his family. But what to her had the appearance of being a disgrace, was a preface of the greatest honours, *Æneas* was carefully educated, and made considerable proficiency in the belles lettres. After having finished his studies at Sienna, he went in 1431 to the council of Bale with Cardinal Capranica, surnamed *De Fermo*, because he was entrusted with the government of that church. *Æneas* was his secretary, and was then only 26 years of age. He afterwards acted in the same capacity to some other prelates, and to Cardinal Albergati. The council of Bale honoured him with different commissions, in order to recompense him for the zeal with which he defended that assembly against Pope Eugene IV. He was afterwards secretary to Frederic III. who decreed to him the poetic crown, and sent him Ambassador to Rome, Milan, Naples, Bohemia, and other places. Nicolas V. advanced him to the bishopric of Trieste, which he quitted some time after for that of Sienna. At last, after having distinguished himself in various nunciatures, he was invested with the Roman purple by Calixtus III. whom he succeeded two years after on the 27th of August 1458. Pius II. now advanced to the holy see, made good the proverb, *Honores mutant mores*. From the commencement of his pontificate, he appeared jealous of the papal prerogatives. In 1460 he issued a bull, "declaring appeals from the pope to a council to be null, erroneous, detestable, and contrary to the sacred canons." That bull, however, did not prevent the procurator-general of the parliament of Paris from appealing to a council in defence of the Pragmatic sanction, which the pope had strenuously opposed. Pius was then at Mantua, whither he had gone in order to engage the Catholic princes to unite in a war against the Turks. The greater part of them agreed to furnish either troops or money; others refused both, particularly the French, who from that moment incurred his holiness's aversion. That aversion abated under Louis XI. whom he persuaded in 1467 to abolish the Pragmatic sanction, which the parliament of Paris had supported with so much vigour.

The following year, 1462, was rendered famous by

Pivat,
Pius.

Pius.

a controversy which took place between the Cordeliers and Dominicans, whether or not the blood of Jesus Christ was separated from his body while he lay in the grave. It was also made a question whether it was separated from his divinity. The Cordeliers affirmed that it was, but the Dominicans were of an opposite opinion. They called each other heretics; which obliged the pope to issue a bull, forbidding them under pain of censure to brand one another with such odious epithets. The bull which his holiness published on the 26th of April, retracting what he had written to the council of Bale when he was its secretary, did not redound much to his honour. "I am a man (says he), and as a man I have erred. I am far from denying that a great many things which I have said and written may deserve condemnation. Like Paul, I have preached through deception, and I have persecuted the church of God through ignorance. I imitate the blessed Augustin, who having suffered some erroneous sentiments to creep into his works, retracted them. I do the same thing; I frankly acknowledge my ignorances, from a fear lest what I have written in my younger years should be the occasion of any error that might afterwards be prejudicial to the interests of the holy see. For if it be proper for any one to defend and support the eminence and glory of the first throne of the church, it is in a peculiar manner my duty, whom God, out of his mercy and goodness alone, without any merit on my part, has raised to the dignity of *vicar of Jesus Christ*. For all these reasons, we exhort and admonish you in the Lord, not to give credit to those writings of ours which tend in any degree to hurt the authority of the apostolic see, and which establish opinions that are not received by the Roman church. If you find, then, any thing contrary to her doctrine either in our dialogues, in our letters, or in any other of our works, despise these opinions, reject them, and adopt our present sentiments. Believe me rather now that I am an old man, than when I addressed you in my earlier days. Esteem a sovereign pontiff more than a private person; except against *Aeneas Sylvius*, but receive Pius II." It might be objected to his holiness, that it was his dignity alone which had made him alter his opinion. He anticipates that objection, by giving a short account of his life and actions, with the whole history of the council of Bale, to which he went with Cardinal Capranica in 1431; "but (says he) I was then a young man, and without any experience, like a bird just come from its nest." In the mean time, the Turks were threatening Christendom. Pius, ever zealous in the defence of religion against the infidels, forms the resolution of fitting out a fleet at the expence of the church, and of passing over into Asia himself, in order to animate the Christian princes by his example. He repaired to Ancona with a design to embark; but he there fell sick with the fatigue of the journey, and died on the 16th of August 1464, aged 59 years. Pius was one of the most learned men of his time, and one of the most zealous pontiffs: but being of an ambitious and pliant disposition, he sometimes sacrificed to that ambition. His principle works are, 1. *Memoirs of the council of Bale*, from the suspension of Eugenius to the election of Felix. 2. *The history of the Bohemians*,

from their origin to the year 1437. 3. *Tractatus de iconography*. 4. *The history of Frederic III.* which vice-chancellor he had been. This performance was published in 1785 in folio, and is believed to be pretty accurate and very particular. 5. *A treatise on the education of children*. 6. *A poem upon the passion of Jesus Christ*. 7. *A collection of 432 letters*, printed at Milan, 1473, in folio, in which are found some curious anecdotes. 8. *The memoirs of his own life*, published by John Gobelin former his secretary, and printed at Rome in 3to in 1584. There is no doubt of this being the genuine production of that pontiff. 9. *Historia rerum ab antiquo gestarum*, of which only the first part was published at Venice in 1477 in folio. His works were printed at Helmstadt in 1700, in folio, at the beginning of which we find his Latin translation of Virgil's *Aeneid* (lib. i. v. 382) which begins thus,

Sunt fides Aeneas,————

and the end of the following vers,

—————*fama super aethera natus,*

have been applied to him.

Pius IV. (John Angel Cardinal de Medicis), of a different family from that of Florence, was born at Milan in 1499. He was son to Bernaudin Medechini, and brother of the famous Marquis de Marignan, Charles Vth's general. He raised himself by his own merit, and filled several important offices under Popes Clement VII. and Paul III. Julius III. who had entrusted him with several legations, honoured him with a cardinal's hat in 1549. After the death of Paul IV. he was advanced to St Peter's chair on the 25th of December 1559. His predecessor had rendered himself detestable to the Romans, who treated his memory with every mark of indignity, and Pius IV. commenced his pontificate by pardoning them. He did not, however, extend the same clemency to the nephews of Pope Paul IV.: for he caused Cardinal Caraffa to be strangled in the castle of St Angel, and his brother, the Prince de Palliano, to be beheaded. His zeal was afterwards directed against the Turks and heretics. In order to stop if possible, the progress of these last, he renewed the Council of Trent, which had been suspended. He knew well (says Abbé de Choisy), that that council might make some regulations which would have the effect to lessen his authority; but on the other hand, he perceived that great inconveniences might result from its not being assembled; and "in the main (said he to his confidants) *it is better to feel evil for once than to be always in dread of it*." In 1561 he dispatched nuncios to all the Catholic and Protestant princes, to present them with the bull for calling that important assembly. An end was, however, put to it by the industry of his nephew, St. Charles Borromeus, in 1563; and, on the 26th of January the year following, he issued a bull for confirming its decrees. In 1565 a conspiracy was formed against his life by Benedict Azoli, and some other visionaries. These madmen had taken it into their head that Pius IV. was not a lawful Pope, and that after his death they would place another in St Peter's chair, with the title of *Pope Angelus*, under whom errors might be reformed, and peace restored to the church. The conspiracy was discovered, and the fanatic Benedict put to death. This pontiff died a little

Pius.

PIUS.

the time after, on the 9th of December 1565, aged 66 years, carrying to the grave with him the hatred of the Romans, whom his severities had exasperated. He was a man of great address, and very fruitful in his resources. He adorned Rome with several public edifices; but these ornaments tended greatly to impoverish it. If he was the instrument of raising his relations in the world, it must be allowed, at least, that the greater part of them did him honour.

PIUS V. (S. Michael Ghisleri), born at Boschi or Boscio, in the diocese of Fortona, on the 17th of January 1504, was, according to Abbé de Choisy, son to a senator of Milan. He turned a Dominican friar. Paul IV. informed of his merit and virtue, gave him the bishopric of Sutri, created him cardinal in 1557, and made him inquisitor-general of the faith among the Milanese and in Lombardy; but the severity with which he exercised his office obliged him to quit that country. He was sent to Venice, where the ardour of his zeal met with still greater obstacles. Pius IV. added to the cardinal's hat the bishopric of Mondovi. After the death of that pontiff, he was advanced to St Peter's chair in 1566. The Romans expressed but little joy at his coronation: he was very sensible of it, and said, "*I hope they will be as sorry at my death as they are at my election;*" but he was mistaken. Raised by his merit to the first ecclesiastical preferment in Christendom, he could not divest himself of the severity of his character; and the situation in which he found himself rendered, perhaps, that severity necessary. One of his first objects was to repress the luxury of the clergy, the pride of the cardinals, and the licentious manners of the Romans. He caused the decrees of reformation enacted by the Council of Trent to be put in execution: he prohibited bull baiting in the Circus; he expelled from Rome the women of the town; and allowed the cardinals to be prosecuted for their debts. The errors which overflowed the Christian world gave him great uneasiness. After having employed gentle and lenient measures in the reclaiming of heretics, he had recourse to severity, and some of them ended their days in the flames of the inquisition. He particularly displayed his zeal for the grandeur of the Holy See in 1568, by ordaining that the bull *In vana domini*, which was published at Rome every year on *Monday Thursday*, and which Clement XIV. suppressed, should be published likewise throughout the whole church. That bull, the work of several sovereign pontiffs, principally regards the jurisdiction of the ecclesiastical and civil power. It anathematizes those who appeal from the decrees of popes to a general council; those who favour the appellants; the universities which teach that the pope is subject to a general council; the princes who would restrain the ecclesiastical jurisdiction, or who exact contributions from the clergy. It was rejected by all the sovereign states, excepting a very few. In 1580, some bishops having endeavoured to introduce it into their dioceses, the parliament caused their temporalities to be seized upon, and declared those guilty of high treason who should imitate the fanaticism of those prelates. Pius V. for some time meditated an expedition against the Turks. He had the courage to make war on the Ottoman empire, by forming a league with the Venetians and Philip II. king of Spain. This was the first time that the standard of the two keys was seen displayed against the

crescent. The naval armies came to an engagement, on the 7th of October 1571, in Lepanto Bay, in which the confederate Christian princes obtained a signal victory over the Turks, who lost above 30,000 men, and near 200 galleys. This success was principally owing to the Pope, who exhausted both his purse and person in fitting out that armament. He died of the gravel six months after, on the 30th of April 1572, aged 68. He repeated often, in the midst of his sufferings, "*O Lord! increase my pains and my patience.*" His name will for ever adorn the List of Roman pontiffs. It is true that his bull against queen Elizabeth, and his other bull in favour of the inquisition, with his rigorous prosecution of heretics both in France and Ireland, prove that he had more zeal than sweetness in his temper; but in other respects he possessed the virtues of a saint and the qualities of a king. He was the model of the famous Sixtus Quintus, to whom he gave an example of amassing in a few years such savings as were sufficient to make the Holy See be regarded as a formidable power. Sultan Selim, who had no greater enemy than this pope, caused public rejoicings to be made at Constantinople for his death during the space of three days. The pontificate of Pius is also celebrated for the condemnation of Baius, the extinction of the order of Humilies, and the reformation of that of the Cistercians. He was canonized by Clement XI. in 1712. There are extant several of his letters, printed at Anvers in 1640, in 4to. Felibian, in 1672, published his *Life*, translated from the Italian of Agatio di Somma; but we cannot vouch for the fidelity of the translation.

PIX. See *MINUT-MARKS*.

PIZARRO (Francis), a celebrated Spanish general, the discoverer and conqueror of Peru, in conjunction with Diego Almagro, a Spanish navigator. They are both charged with horrid cruelties to the inhabitants; and they fell victims to their own ambition, jealousy, and avarice. Almagro revolting, was defeated and beheaded by Pizarro, who was assassinated by Almagro's friends in 1541. See *PERU*.

PLACE, LOCUS, in philosophy, a mode of space, or that part of immoveable space which any body possesses. See *METAPHYSICS*, n^o 185.

PLACE in astronomy. The place of the sun, a star, &c. denotes the sign and degree of the zodiac which the luminary is in; or the degree of the ecliptic, reckoning from the beginning of aries, which the planet or star's circle of longitude cuts: and therefore coincides with the longitude of the sun, planet, or star. As the sine of the sun's greatest declination 23° 30': to the sine of any present declination given or observed, for instance, 23° 15' :: 10 is the radius 10 : to the sine of his longitude 81° 52'; which, if the declination were north, would give 20° 52' of gemini; if south, 20° 52' of capricorn, for the sun's place. See *DECLINATION*, &c.

The place of the moon being that part of her orbit wherein she is found at any time, is of various kinds, by reason of the great inequalities of the lunar motions, which render a number of equations and reductions necessary before the just point be found. The moon's fictitious place is her place once equated; her place nearly true, is her place twice equated; and her true place thrice equated. See *ASTRONOMY*, *passim*.

PLACE, in war, a general name for all kinds of fortifications

PIUS.

Place.

Place
||
Placentia.

treffes where a party may defend themselves. Thus,
1. A strong or fortified place is one flanked, and covered with bastions. 2. A regular place, one whose angles, sides, bastions, and other parts, are equal; and this is usually denominated from the number of its angles, as a pentagon, hexagon, &c. 3. Irregular place is one whose sides, and angles are unequal.— 4. Place of arms is a strong city or town pitched upon for the chief magazine of an army; or, in a city or garrison, it is a large open spot of ground, usually near the centre of the place where the grand guard is commonly kept, and the garrison holds its rendezvous at reviews, and in cases of alarm to receive orders from the governor. 5. Places of arms of an attack, in a siege, is a spacious place covered from the enemy by a parapet or epaulement, where the soldiers are posted ready to sustain those at work in the trenches against the soldiers of the garrison. 6. Place of arms particular, in a garrison, a place near every bastion, where the soldiers sent from the grand place to the quarters assigned them relieve those that are either upon the guard or in sight. 7. Place of arms without, is a place allowed to the covert way for the planting of cannon, to oblige those who advance in their approaches to retire. 8. Place of arms in a camp, a large place at the head of the camp for the army to be ranged in and drawn up in battalia. There is also a place for each particular body, troop, or company, to assemble in.

Common-Place. See *COMMON-Place.*

PLACENTA, in anatomy and midwifery, a soft roundish mass, found in the womb of pregnant women which, from its resemblance to the liver, was called by the ancients *hepar uterinum*, uterine liver.

PLACENTIA, called by the natives *Piacenza*, is a town of Italy, and capital of a duchy of the same name, with a bishop's see. It is seated about 100 paces from the river Po, in a very fertile pleasant plain, watered by a great number of rivulets, and surrounded with hills, abounding in all sorts of fruits. In its territory there are salt-springs, from which they make a very white salt; and there are also mines of iron, woods, and warrens. It contains a great number of merchants, and is reckoned three miles in circumference. Its fortifications are inconsiderable, but the citadel is pretty strong. The streets are straight, and the principal street, called *Stradone*, is 25 common paces broad and 3000 feet long, in a direct line, with 600 stone posts, for separating the foot from the carriage-way, and on both sides are 11 spacious convents. The other buildings of the city are not very remarkable, though it contains 45 churches, 28 convents, and two alms-houses. The cathedral is pretty much in the Gothic taste; but the church of the Augustines is reckoned the most beautiful, and esteemed worthy of its architect, the celebrated Vignoli. The ducal palace, though large, makes no great appearance on the outside; but within are some good apartments. In the area before the town-house stand two admirable brass statues of Alexander and Renatus IV. both of the house of Farnese, and dukes of Parma and Placentia. The bishop is suffragan to the archbishop of Milan. At this city begins the *Via Æmilia*, which extends as far as Rimini on the Adriatic. The number of the inhabitants is about 30,000, among whom there are 2000

VOL. XIV.

ecclesiastics. This city has been taken several times in the wars of Italy. The king of Sardinia took possession of it in 1744, it being ceded to him by the queen of Hungary; but it was taken from him in 1746, after a bloody battle. It has a famous university, and the inhabitants are much esteemed for their politeness. There is a great fair here every year on the 15th of April, which is much frequented. It is about 32 miles north-west of Parma and 83 east of Turin. E. Long. 10. 24. N. Lat. 45. 5.

PLAGIARY, in philology, the pilfering another man's works, and putting them off as our own. Among the Romans, *plagiarius* was properly a person who bought, sold, or retained a freeman for a slave; and was so called, because, by the Flavian law, such persons were condemned *ad plagas*, "to be whipped."

Thomasius has an express treatise *De plagio literario*; wherein he lays down the laws and measures of the right which authors have to one another's writings "Dictionary-writers, at least such as meddle with *arts and sciences* (as is pertinently observed by Mr Chambers), seem exempted from the common laws of *meum and tuum*; they do not pretend to set up on their own bottom, nor to treat you at their own cost. Their works are supposed, in great measure, compositions of other people's; and what they take from others; they do it avowedly, and in the open sun.—In effect, their quality gives them a title to every thing that may be for their purpose, wherever they find it; and if they rob, they do not do it any otherwise than as the bee does, for the public service. Their occupation is not pillaging, but collecting contributions; and if you ask them their authority, they will produce you the practice of their predecessors of all ages and nations."

PLAGIUM, in law. See KIDNAPPING.

PLAGUE, PESTILENCE, or *Pestilential Fever*, is a very acute, malignant, and contagious disease; being a putrid fever of the worst kind, and seldom failing to prove mortal. Though it is generally defined a malignant fever, Diemerbroek thinks they ought to be distinguished, since the fever is not the essence of the disease, but merely a symptom or effect of it. See *MEDICINE*, n^o 221.

The plague, as is generally agreed, is never bred or propagated in Britain, but always imported from abroad especially from the Levant, Lesser Asia, Egypt, &c. where it is very common. Sydenham has remarked that it rarely infects this country oftener than once in 40 years, and happily we have been free of it for a much longer period.

Authors are not as yet agreed concerning the nature of this dreadful distemper. Some think that insects are the cause of it, in the same way that they are the cause of blights, being brought in swarms from other climates, by the wind, when they are taken into the lungs in respiration; the consequence of which is, that they mix with the blood and juices, and attack and corrode the viscera. Mr Boyle, on the other hand, thinks it originates from the effluvia or exhalations breathed in the atmosphere, from noxious minerals, to which may be added stagnant waters and putrid bodies of every kind.

Mr Gibbon thinks that the plague is derived from damp, hot, and stagnating air, and the putrefaction

Plagiary
||
Plague.

Plague. of animal substances, especially locusts. See *Gibbon's Roman History*, 4to edit. vol. iv. p. 327—332, where there is also a very particular account of the plague which depopulated the earth in the time of the Emperor Justinian.

The Mahometans believe that the plague proceeds from certain spirits, or goblins, armed with bows and arrows, sent by God to punish men for their sins; and that when the wounds are given by spectres of a black colour, they certainly prove fatal, but not so when the arrows are shot by those that appear white. They therefore take no precaution to guard themselves against it. The wiser professors of this religion, however, at present act otherwise; for we find a receipt recommended by Sidy Mohammed Zerroke, one of the most celebrated Marabout's, prefaced with these remarkable words; "The lives of us all are in the hands of God, when it is we must die. However, it hath pleased him to save many persons from the plague, by taking every morning while the infection rages one pill or two of the following composition; *viz.* of myrrh two parts, saffron one part, of aloes two parts, of syrup of myrtle-berries, *q. s.* But this remedy is confined to the more enlightened; for the bigotry of the lower sort is so extreme as to make them despise all precautions which people of other nations use. Of this extreme and foolish prejudice Dr Chandler gives an interesting account when speaking of the plague at Smyrna. This learned author is of opinion that the disease arises from animalcules, which he supposes to be invisible. See *Chandler's Travels in Asia Minor*, p. 279, &c.

It is a remarkable fact, that *plagues* are sometimes partial, and that they only attack particular animals, or a particular description of persons, avoiding others altogether, or attacking them but slightly. Thus Fernelius informs us of a plague, or murrain, in 1514, which invaded only cats. Dionysius Halicarnassensis mentions a plague which attacked none but maids; and that which raged in the time of Genesis, killed scarce any women, and very few but lusty men. Bosterus mentions another plague, which assailed none but the younger sort: and we have instances of the same kind of a later standing (A). Cardon speaks of a plague at Basil, with which the Switzers were infected, and the Italians, Germans, or French, exempted: and John Utenhovius takes notice of a dreadful one at Copenhagen, which, tho' it raged among the Danes, spared the Germans, Dutch, and English, who went with all freedom, and without the least danger, to the houses of the infected. During the plague which ravaged Syria in 1760, it was observed that people of the soundest constitutions were the most liable to it, and that the weak and delicate were either spared or easily cured. It was most fatal to the Moors; and when it attacked them it was generally incurable.

When the plague raged in Holland in 1636, a young girl was seized with it, had three carbuncles, and was removed to a garden, where her lover, who was betrothed to her, attended her as a nurse, and slept with her as his wife. He remained uninfected, and she recovered, and was married to him. The story is related

by Vinc. Fabricius in the *Misc. Cur. Ann.* II. *Obs.* 188.

Many methods have been adopted in different countries to prevent the importation of this dreadful scourge of the human race, and to stop the progress of infection after it has been imported. In England, mayors, bayliffs, head officers of corporations, and justices, of peace, have power to tax inhabitants, houses and lands, &c. within their precincts, for the relief of persons infected with the plague; and justices of the county may tax persons within five miles round, on a parish's inability; the tax to be levied by distress and sale of goods, or in default thereof by imprisonment. Infected persons going abroad after being commanded to keep house for avoiding farther infection, may be resisted by watchmen, &c. and punished as vagrants, if they have no fores upon them; and if they have infectious fores on them it is felony. Justices of peace, &c. are to appoint searchers, examiners, and buriers of the dead, in places infected, and administer oaths to them for the performance of their duties, &c. *stat. 1. Jac. 1. cap. 31.* See QUARANTINE.

The commission at Moscow having, in the year 1770, invented a fumigation-powder, which, from several lesser experiments, had proved efficacious in preventing the infection of the plague; in order more fully to ascertain its virtue in that respect, it was determined, towards the end of the year, that ten malefactors under sentence of death should, without undergoing any other precautions than the fumigations, be confined three weeks in a lazaretto, be laid upon the beds and dressed in the clothes, which had been used by persons sick, dying, and even dead, of the plague in the hospital. The experiment was accordingly tried, and none of the ten malefactors were then infected, or have been since ill. The fumigation powder is prepared as follows.

Powder of the first strength.] Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum-wood pounded, of each six-pounds; common salt-petre pounded, eight pounds; sulphur pounded, six pounds; Smyrna tar, or myrrh, two pounds; mix all the above ingredients together, which will produce a pood of the powder of fumigation of the first strength. [N. B. A pood is 40 pounds Russian, which, are equal to 35 pounds and a half or 36 pounds English avoirdupoise.]

Powder of the second strength.] Take southernwood cut into small pieces, four pounds; juniper-berries pounded, three pounds; common salt-petre pounded, four pounds; sulphur pounded, two pounds and a half; Smyrna tar, or myrrh, one pound and a half; mix the above together, which will produce half a pood of the powder of fumigation of the second strength.

Oderiferous Powder.] Take the root called *kalmus* cut into small pieces, three pounds; leaves of juniper cut into small pieces, four pounds; frankincense pounded grossly, one pound; storax pounded, and rose-flowers, half a pound; yellow amber pounded, one pound; common salt-petre pounded, one pound and a half; sulphur, a quarter of a pound; mix all the above

(A) See the account of the *yellow fever* under the article PHILADELPHIA, where we find that that disease was less fatal to some sorts of persons than to others.

Plague. above together, which will produce nine pounds and three quarters of the odoriferous powder.

Remark on the powder of fumigation.] If guaiacum cannot be had, the cones of pines or firs may be used in its stead; likewise the common tar of pines and firs may be used instead of the Smyrna tar, or myrrh, and tangwort may supply the place of southern wood.

Thucydides, who was himself infected, lib. ii. gives us an account of a dreadful plague which happened at Athens about the year before Christ 430, while the Peloponnesians under the command of Archidamus wasted all her territory abroad; but of these two enemies the plague was by far the most dreadful and fevere.

The most dreadful plague that ever raged at Rome was in the reign of Titus, A. D. 80. The emperor left no remedy unattempted to abate the malignity of the distemper, acting during its continuance like a father to his people. The same fatal disease raged in all the provinces of the Roman empire in the reign of M. Aurelius, A. D. 167, and was followed by a dreadful famine, by earthquakes, inundations, and other calamities. The Romans believed that Æsculapius sometimes entered into a serpent, and cured the plague.

About the year 430 the plague visited Britain, just after the Picts and Scots had made a formidable invasion of the southern part of the island. The plague raged with uncommon fury, and swept away most of those whom the sword and famine had spared, so that the living were scarce sufficient to bury the dead.

About the year 1348 the plague became almost general over Europe. A great many authors give an account of this plague, which is said to have appeared first in the kingdom of Kathay in the year 1346, and to have proceeded gradually westward to Constantinople and Egypt. From Constantinople it passed into Greece, Italy, France and Africa, and by degrees along the coasts of the ocean into Britain and Ireland, and afterwards into Germany, Hungary, Poland, Denmark, and the other northern kingdoms. According to Antoninus archbishop of Florence the distemper carried off 60,000 people in that city, among whom was the historian John Villani.

In the year 1656 the plague was brought from Sardinia to Naples, being introduced into the city by a transport with soldiers on board. It raged with excessive violence, carrying off in less than six months 400,000 of the inhabitants. The distemper was at first called by the physicians a malignant fever; but one of them affirming it to be pestilential, the viceroy, who was apprehensive lest such a report would occasion all communication with Naples to be broke off, was offended with this declaration, and ordered him to be imprisoned. As a favour, however, he allowed him to return and die in his own house. By this proceeding of the viceroy, the distemper being neglected, made a most rapid and furious progress, and filled the whole city with consternation. The streets were crowded with consular processions, which served to spread the infection through all the quarters. The terror of the people increased their superstition; and it being reported that a certain nun had prophesied that the pestilence would cease upon building a hermitage for her sister upon the hill of St Martin's, the edifice was immediately begun with the most ardent zeal. Persons of the highest quality strove who should per-

form the meanest offices; some loading themselves with beams, and others carrying baskets full of lime and nails, while persons of all ranks stripped themselves of their most valuable effects, which they threw into empty hogsheds placed in the streets to receive the charitable contributions. Their violent agitation, however, and the increasing heats, diffused the malady through the whole city, and the streets and the flairs of the churches were filled with the dead; the number of whom, for some time of the month of July, amounted daily to 15,000.

The viceroy now used all possible precautions to abate the fury of the distemper, and to prevent its spreading to the provinces. The infection however, desolated the whole kingdom, excepting the provinces of Otranto and the Farther Calabria, and the cities of Gaeta, Sorrento, Paolo, and Belvedere. The general calamity was increased in Naples by malecontents, who insinuated that the distemper had been designedly introduced by the Spaniards, and that there were people in disguise who went through the city sowing poisoned dust. This idle rumour enraged the populace, who began to insult the Spanish soldiers, and threaten a sedition; so that the viceroy, to pacify the mob, caused a criminal to be broke upon the wheel, under pretence that he was a dissemer of the dust. A violent and plentiful rain falling about the middle of August, the distemper began to abate; and on the eighth of December the physicians made a solemn declaration that the city was entirely free from infection.

Of the dreadful plague which raged at London in the year 1665, the reader will find an account in the article *London*, n^o 21. In 1720 the city of Marseilles was visited with this destructive disease, brought in a ship from the Levant; and in seven months, during which time it continued, it carried off not less than 60,000 people. This desolation is not yet obliterated from the minds of the inhabitants; some survivors remained alive but a few years ago to transmit a traditional account of it to after ages. There are two fine pictures painted by Puget representing some of the horrid scenes of that time. "They are (says lady Craven) only too well executed. I saw several sick figures taking leave of their friends, and looking their last anxious, kind, and wishful prayers on their dying infants, that made the tears flow down my cheeks. I was told the physicians and noblemen who were assisting the sick and dying, were all portraits: I can easily conceive it; for in some faces there is a look of reflection and concern which could only be drawn from the life." *Letters*, p. 34, 35. This fatal event has caused the laws of quarantine to be very strictly enforced in the Lazaretto here, which is an extensive insulated building.

The ravages of this disease have been dreadful wherever it has made its appearance. On the first arrival of the Europeans at the island of Gran Canaria, it contained 14,000 fighting men, soon after which, two thirds of the whole inhabitants fell a sacrifice to the plague, which had doubtless been introduced by their new visitors. The destruction it has made in Turkey in Europe, and particularly in Constantinople, must be known to every reader; and its fatal effects have been particularly heightened there by that firm belief which prevails among the people of predestination, &c. as has been already mentioned. It is generally
brought

brought into European Turkey from Egypt; where it is very frequent, especially at *Grand Cairo*. To give even a list of all the plagues that have desolated many flourishing countries, would extend this article beyond all bounds, which minutely to describe them all would be impossible. For the plague at Smyrna we refer to Chandler's Travels as above. Respecting that which raged in Syria in 1760, we refer to the Abbé Mariti's Travels through Cyprus, Syria, and Palestine, vol. 1st, p. 273—296. This plague was one of the most malignant and fatal that Syria ever experienced; for it scarcely made its appearance in any part of the body when it carried off the patient.

PLAIN, or PLANE, in general, an appellation given to whatever is smooth and even, or simple, obvious, and easy to be understood; and, consequently, stands opposed to rough, enriched, or laboured.

A plain figure, in geometry, is an uniform surface; from every point of whose perimeter right lines may be drawn to every other point in the same.

A plain angle is one contained under two lines, or surfaces, in contradistinction to a solid angle. See ANGLE.

The doctrine of plain triangles, as those included under three right lines, is termed *plain trigonometry*. See the article TRIGONOMETRY.

PLAIN Chart. See the article CHART.

PLAIN-Sailing. See NAVIGATION, p. 685.

PLAISE, the English name of a species of pleuronectes. See PLEURONECTES.

PLAN, in general, denotes the representation of something drawn on a plane; such are maps, charts, ichnographies, &c. See MAP, CHART, &c.

The term *plan*, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground, showing the extent, division, and distribution of its area or ground-plot into apartments, rooms, passages, &c.

A geometrical plan is that wherein the solid and vacant parts are represented in their natural proportions.

The raised plan of a building is the same with what is otherwise called an *elevation* or *orthography*. See ORTHOGRAPHY.

A perspective plan is that exhibited by degradations or diminutions, according to the rules of perspective. See PERSPECTIVE.

To render plans intelligible, it is usual to distinguish the masses with a black wash; the projections on the ground are drawn in full lines, and those supposed over them in dotted lines. The augmentations or alterations to be made are distinguished by a colour different from what is already built; and the tints of each plan made lighter as the stories are raised.

In large buildings it is usual to have three several plans for the three first stories.

PLANCUS (Francis), doctor of physic, born at Amiens in 1696, and who died on the 19th of September 1765, aged 69 years, is author of some works which do honour to his memory. 1. A complete System of Surgery, in 2 vols. in 12mo; a treatise much recommended by surgeons to their pupils. 2. A choice Library of Medicine, taken from periodical publications, both French and others: this curious collection,

continued and completed by M. Goulin, makes 9 vols in 4to, or 18 vols in 12mo. 3. A Translation of Vander Wiel's Observations on Medicine and Surgery, 1758, 2 vols in 12mo. Plancus was the editor of various editions of works on medicine and surgery, and enriched them with notes. He shut himself up in his study for a long time before he practised his profession.

PLANE, in geometry, denotes a plane surface, or one that lies evenly between its bounding lines: and as a right line is the shortest extension from one point to another, so a plane surface is the shortest extension from one line to another.

In astronomy, conics, &c. the term *plane* is frequently used for an imaginary surface, supposed to cut and pass through solid bodies: and on this foundation is the whole doctrine of conic sections built. See ASTRONOMY, CONIC SECTIONS, &c.

In mechanics planes are either horizontal, that is, parallel to the horizon, or inclined thereto. See MECHANICS.

The determining how far any given plane deviates from an horizontal line, makes the whole business of levelling. See the article LEVELLING.

In optics, the planes of reflection and refraction are those drawn through the incident and reflected or refracted rays. See OPTICS.

In perspective we meet with the perspective plane, which is supposed to be pellucid, and perpendicular to the horizon; the horizontal plane, supposed to pass through the spectator's eye, parallel to the horizon; the geometrical plane, likewise parallel to the horizon, wherein the object to be represented is supposed to be placed, &c. See PERSPECTIVE.

The plane of projection in the stereographic projection of the sphere, is that on which the projection is made, corresponding to the perspective plane. See PROJECTION.

PLANE, in joinery, an edged tool or instrument for parting and shaving of wood smooth.—It consists of a piece of wood very smooth at bottom, has a stock or shaft; in the midst of which is an aperture, through which a steel edge, or chisel, placed obliquely, passes; which, being very sharp, takes off the inequalities of the wood along which it slides.

PLANE-Tree, in botany. See PLATANUS.

PLANET, a celestial body, revolving round the sun as a centre, and continually changing its position with respect to the fixed stars; whence the name *planet*, which is a Greek word, signifying "wanderer."

The planets are usually distinguished into primary and secondary. The primary ones, called by way of eminence *planets*, are those which revolve round the sun as a centre; and the secondary planets, more usually called *satellites* or *moons*, are those which revolve round a primary planet as a centre, and constantly attend it in its revolution round the sun.

The primary planets are again distinguished into superior and inferior. The superior planets are those farther from the sun than our earth; as Mars, Jupiter, Saturn, and the Georgium Sidus; and the inferior planets are those nearer the sun than our earth, as Venus and Mercury. See ASTRONOMY.

That the planets are opaque bodies like our earth, is thought probable for the following reasons, 1. Since in Venus, Mercury, and Mars, only that part of the disk

Plane,

Planetary.

disk illuminated by the sun is found to shine : and again, Venus and Mercury, when between the earth and the sun, appear like dark-spots or maculæ on the sun's disk ; it is evident, that Mars, Venus, and Mercury, are opaque bodies, illuminated with the borrowed light of the sun. And the same appears of Jupiter, from its being void of light in that part to which the shadow of the satellites reaches, as well as in that part turned from the sun ; and that his satellites are opaque, and reflect the sun's light, is abundantly shown. Again, since Saturn, with his ring and satellites, only yield a faint light, fainter considerably than that of the fixed stars, though these be vastly more remote, and than that of the rest of the planets ; it is past doubt that he too with his attendants are opaque bodies. 2. Since the sun's light is not transmitted through Mercury and Venus when placed against him, it is plain they are dense opaque bodies ; which is likewise evident of Jupiter, from his hiding the satellites in his shadow ; and therefore, by analogy, the same may be concluded of Saturn. 3. From the variable spots of Venus, Mars, and Jupiter, it is evident these planets have a changeable atmosphere ; which changeable atmosphere may, by a like argument, be inferred of the satellites of Jupiter ; and therefore, by similitude, the same may be concluded of the other planets. 4. In like manner, from the mountains observed in Venus, the same may be supposed in the other planets. 5. Since, then, Saturn, Jupiter, and the satellites of both, Mars, Venus, and Mercury, are opaque bodies shining with the sun's borrowed light, are furnished with mountains, and encompassed with a changeable atmosphere ; they have, of consequence, waters, seas, &c. as well as dry land, and are bodies like the moon, and therefore like the earth. *Q. E. D.* And hence it seems also highly probable, that, the other planets have their animal inhabitants as well as our earth.

PLANETARIUM, an astronomical machine so called from its representing the motions, orbits, &c. of the planets, agreeable to the Copernican system. See **ASTRONOMY**, n^o 489 and Plate LXXXVIII.

PLANETARY, something that relates to the planets. Hence we say, planetary worlds, planetary in-

habitants, &c. Huygens and Fontenelle bring several probable arguments for the reality of planetary animals, plants, men, &c. See **PLANET**.

PLANETARY System, is the system or assemblage of the planets, primary and secondary, moving in their respective orbits, round their common centre the sun. See **ASTRONOMY**.

PLANETARY Days.—Among the ancients, the week was shared among the seven planets, each planet having its day. This we learn from Dion Cassius and Ptolemy, *Sympof.* l. 4. q. 7. Herodotus adds, that it was the Egyptians who first discovered what god, that is, what planet, presides over each day ; for that among this people the planets were directors. And hence it is, that in most European languages the days of the week are still denominated from the planets ; Sunday, Monday, &c. See **WEEK**.

PLANETARY Years, the periods of time in which the several planets make their revolutions round the sun or earth.—As from the proper revolution of the sun, the solar year takes its original ; so from the proper revolutions of the rest of the planets about the earth, so many sorts of years do arise, viz. the Saturnian year, which is defined by 29 Egyptian years, 174 hours, 58 minutes, equivalent in a round number to 30 solar years.—The Jovial year, containing 317 days, 14 hours, 59 minutes.—The Martial year, containing 321 days, 23 hours, 31 minutes.—For Venus and Mercury, as their years, when judged of with regard to the earth, are almost equal to the solar year ; they are more usually estimated from the sun, the true centre of their motions : in which case, the former is equal to 224 days, 16 hours, 40 minutes ; the latter to 87 days, 23 hours, 14 minutes.

PLANIMETRY, that part of geometry which considers lines and plain figures, without considering their height or depth. See **GEOMETRY**.

PLANISPHERE, signifies a projection of the sphere, and its various circles on a plane ; in which sense, maps, whereon are exhibited the meridians and other circles of the sphere, are planispheres. See **MAP**.
